Summary

This study is the first to isolate an *Entamoeba histolytica* strain from Chinese amoebic patients and to conduct a detailed examination of its virulence. A fecal sample that contains cysts of *E. histolytica* was obtained from Guangxi province. The sample was cultured axenically and then cloned by limiting dilution, and named as XLAC. *In vitro* and *in vivo* tests were conducted to evaluate the virulence of the *Entamoeba* isolate. The *E. histolytica* strain XLAC was successfully cloned and cultured axenically. DNA regions that contain hexokinase, glucose-6-phosphate isomerase, phosphoglucomutase, and heavy subunit of lectin genes were amplified by PCR. The PCR products were then sequenced. Virulence analysis suggested that the XLAC strain was similar to the HM1:IMSS strain at the genetic level. *In vitro* and *in vivo* tests also implicated these strains to be similar. These findings may be attributed to the low expression levels of pathogenic genes obtained through real-time PCR. The XLAC strain restored its virulence after it was injected into hamster liver. This study may be a good model for studying virulence changes in *E. histolytica*.

**Keywords:** *Entamoeba histolytica*, lectin, apoptosis, virulence

1. Introduction

The enteric protozoan parasite *Entamoeba histolytica* causes an estimated 50 million cases of amebic colitis and extraintestinal abscess, which result in 100,000 deaths annually (1). *Entamoeba dispar* is morphologically indistinguishable from *E. histolytica*, but it is nonpathogenic (2,3). *E. histolytica* infections have different clinical outcomes. Most infections remain asymptomatic, whereas some infected patients develop diarrhea and dysentery. Only a few infections develop extra-intestinal complications, such as liver abscess.

Several *E. histolytica* infections in China are reported every year. The average infection rate of amebiasis in China was 0.949% in the 1990s. A 2006 survey of HIV-positive patients in China showed a serum-positive rate of 7.9% for *E. histolytica* (4). A recent study in seven provinces in China has shown a serum-positive rate of 0.53% to 9.04% for *E. histolytica* (5). However, insufficient pathogenic information on Chinese *E. histolytica* strains is currently available. The *E. histolytica* strain utilized in the current paper was obtained from Guangxi Province. *In vitro* and *in vivo* tests were conducted to evaluate the virulence of the *Entamoeba* isolate.

2. Materials and Methods

2.1. Sample collection

Stool and blood samples were obtained from 120 villagers in August, 2011 in Xilin County, Guangxi Province, China.

2.2. Indirect fluorescence antibody assay (IFA)

The IFA test was performed as previously described using formalin-fixed trophozoites smeared on glass
slides. Fluorescein isothiocyanate-conjugated goat immunoglobulin G (IgG) to whole human IgG (MP Biomedicals-Cappel, Solon, OH, USA) was used as the second antibody.

2.3. Culture conditions

A fecal sample that contains Entamoeba cysts was suspended in water for 24 h to remove Blastocystis spp. The sample was then cultured in modified Tanabe-Chiba medium (6) at 37°C. The trophozoites were treated with a cocktail of antibiotics and then cultured monoxenically with live Crithidia fasciculata in TYI-S-33 medium supplemented with 15% adult bovine serum (Gibco, Life Technologies, Carlsbad, CA, USA) at 37°C. The trophozoites of the strain were cultured axenically in TYI-S-33 medium and then cloned through limited dilution.

2.4. PCR analysis and sequence

Genomic DNA was extracted from the axenic cultures using a QIAamp DNeasy kit (Qiagen, Valencia, CA, USA) (7). The genomic DNA was subjected to PCR for the amplification of hexokinase (HXK), glucose-6-phosphate isomerase (GPI), phosphoglucomutase (PGM), and heavy subunit of lectin genes (LecHgl). The primers and PCR conditions for E. histolytica were based on previously described procedures (8,9). PCR was performed briefly in a 50 μL reaction mixture using TaKaRa Ex-taq® DNA Polymerase (Takara, Dalian, China).

The PCR products were subjected to direct sequencing after purification using a QIAquick PCR purification kit (Qiagen) using a BigDye Terminator v3.1 Cycle sequencing kit (Applied Biosystems, Carlsbad, CA, USA). The reactions were run on an ABI Prism 3100 Genetic Analyzer (Applied Biosystems). Sequence data were analyzed using ClustalX Ver. 1.83 (Conway Institute UCD Dublin, Dublin, Ireland).

2.5. Erythrocyphagocytosis assay

Type O human erythrocytes from healthy donors were washed and suspended in TYI-S-33 medium. Erythrocytes (2 × 10⁸) were incubated with 2 × 10⁶ trophozoites in 0.4 mL TYI-S-33 medium at 37°C for 10 min. After being lysed with free and adherent erythrocytes through the addition of distilled water, the trophozoites were fixed and stained with a 3,3-diaminobenzidine (Sigma-Aldrich, St. Louis, MO, USA) solution containing hydrogen peroxide (Sinopharm Group Co. Ltd., Shanghai, China). The number of ingested erythrocytes was determined by examining 300 trophozoites. The experiments were repeated three times. Statistical analysis was performed using Student’s t-test.

2.6. Erythrocyte adherence assay

The trophozoites (2 × 10⁶) were incubated with 2 × 10⁷ type O human erythrocytes for 5 min at 4°C. The erythrocyte-trophozoite suspension was then fixed in 2.5% glutaraldehyde (Sigma-Aldrich). Afterwards, the erythrocytes were washed with PBS and stained with a 3,3-diaminobenzidine (Sigma-Aldrich) solution containing 0.2% H₂O₂ (Sinopharm Group Co. Ltd.). The number of amoeba with at least three erythrocytes was scored by examining 300 trophozoites. The experiments were repeated three times. Statistical analysis was performed using Student’s t-test.

2.7. Apoptosis in Jurkat cells

Entamoeba trophozoites were washed with and suspended in RPMI 1640 medium (Gibco, Life Technologies). The trophozoites (2 × 10⁶) were incubated with 10⁵ Jurkat cells (The Cell Bank of Chinese Academy of Science, Shanghai, China) for 20 min at 37°C. The cells were then washed twice and stained with FITC-conjugated annexin V (Sigma-Aldrich). The numbers of apoptosis and total cells were determined under a microscope. The experiments were repeated three times. Statistical analysis was performed using Student’s t-test.

2.8. Expression of the heavy subunit of lectin genes

Total RNAs of E. histolytica trophozoites were isolated using an RNeasy mini kit (Qiagen) and used for cDNA synthesis using a GeneAmp RNA PCR kit (Applied Biosystems). A reaction mixture that contains SYBR Premix Ex Taq (Takara), specific primers, and the cDNAs was used for quantitative real-time PCR analysis. The primer pairs used were previously described (10). Forty cycles of amplification were performed using the ABI PRISM 7500 Sequence Detection System (Applied Biosystems). The fluorescence intensity in each cycle was also recorded using the ABI PRISM 7500 Sequence Detection System (Applied Biosystems). The relative quantification of the data obtained from the ABI PRISM 7500 Sequence Detection System software version 2.0.1 (Applied Biosystems) was performed by the comparative CT method using actin genes as internal standards. The experiments, including the culture of trophozoites and the isolation of RNA, were repeated three times.

2.9. Hepatic challenge with E. histolytica

Sixteen 6-week-old male hamsters (Shanghai Songlian Experimental Animal Farm, Shanghai, China) were used. The hamsters were challenged with intrahepatic inoculation of 10⁸ E. histolytica trophozoites into the left lobe of the liver. The hamsters were sacrificed 7 d after the challenge. The percentage of the abscessed
3. Results and Discussion

The present study was processed during 2012. Among the 120 stool samples, 11 were discovered to be positive for Entamoeba species by microscopy. One E. histolytica infection, named XLAC, was finally defined via the IFA assay. The XLAC strain was successfully cloned and cultured axenically.

The DNA regions of the XLAC strain that contain LecHgl and isozyme genes were amplified by PCR. The PCR products were sequenced directly. The nucleotide sequences of the LecHgl, HXK, and PGM genes from XLAC were identical to those of the HM1:IMSS strain. The nucleotide sequences of the GPI gene from XLAC were identical to those of the SFL-3 and BF-841 strains. These sequences had one nucleotide substitution. However, no differences in amino acid sequences were observed between the XLAC and HM1:IMSS strains.

The XLAC strain was evaluated for erythrophagocytosis. The SAW755CR strain was used as the control. The rates of erythrocyte-ingesting trophozoites of the XLAC and SAW755CR strains were 30.7% and 79.3%, with 1.1 and 5.7 ingested erythrocytes per trophozoite, respectively (Figure 1A). A significant difference in erythrophagocytosis was observed between the XLAC and SAW755CR strains (p < 0.001).

The adherence of the XLAC and SAW755CR strains to human erythrocytes is shown in Figure 1B. The adherence rates of the trophozoites of the XLAC and SAW755CR strains to human erythrocytes were 16.3% and 47.4%, respectively. A significant difference in adherence was found between the XLAC and SAW755CR strains (p < 0.001).

Jurkat cells were incubated with E. histolytica trophozoites for 20 min at a 5:1 ratio. The relative apoptosis rates to the blank control of the XLAC and SAW755CR strains were 17.8% and 35.2%, respectively (Figure 2). A significant difference in the relative apoptosis rate was observed between the XLAC and SAW755CR strains (p < 0.001).

The liver was calculated as the weight of the abscess divided by the recorded weight of the liver before abscess removal. The E. histolytica trophozoites were again subjected to the erythrophagocytosis assay after being injected into hamster liver.

Figure 1. Erythrophagocytosis and erythrocyte adherence of Entamoeba histolytica. (A), Erythrophagocytosis of E. histolytica XLAC and SAW755CR strains. (B), Erythrocyte adherence of E. histolytica XLAC and SAW755CR strains. *p < 0.001.

Figure 2. Apoptosis in Jurkat cells. Jurkat cells were incubated with E. histolytica trophozoites for 20 min at a 5:1 ratio. The relative apoptosis rates to the blank control of the XLAC and SAW755CR strains were 17.8% and 35.2%, respectively. *p < 0.001.

Figure 3. Expression of the heavy subunit of lectin genes. The quantitative expression of the LecHgl gene in the XLAC and SAW755CR strains was measured. Real-time reverse transcription PCR was performed using actin genes as internal standards. The mean value of the relative expression level of XLAC LecHgl to SAW755CR LecHgl was estimated to be 0.669. *p < 0.001.
Real-time reverse transcription PCR was performed to measure quantitatively the expression of the LecHgl genes in the XLAC and SAW755CR strains. The results were analyzed by the comparative CT method using actin genes as internal standards. The experiments were repeated in triplicate. The mean value of the relative expression level of XLAC LecHgl to SAW755CR LecHgl was estimated to be 0.669 (Figure 3). A significant difference in the expression level of LecHgl was found between the XLAC and SAW755CR strains ($p < 0.001$).

Ten hamsters developed amebic liver abscesses 7 d after they were challenged with an intrahepatic inoculation of XLAC strain trophozoites. The mean mass of the abscesses was 21.7% of the liver mass (Table 1). By contrast, no amebic liver abscess formation was observed in the PBS control group. The presence of erythrophagocytosis in the XLAC strain after passage hamster liver was also evaluated. The original XLAC strain was used as the control. The rate of erythrocyte ingestion after trophozoite passage hamster liver was 61.7%, which was higher than the 37.7% rate of the original XLAC strain. The number of ingested erythrocytes after XLAC trophozoite passage hamster liver was 2.3 per trophozoites, which was higher than the 1.15 per trophozoites of the original XLAC strain. The XLAC strain restored its virulence after being injected into hamster liver.

The ability of *E. histolytica* trophozoites to invade the colon and other tissues depends on several pathogenic factors. One of the most important factors is the galactose- and $N$-acetyl-D-galactosamine-inhibitable cell surface lectin of the ameba. The lectin mediates the adherence of trophozoites to human colonic mucins, colonic epithelial cells, neutrophils, and erythrocytes. The lectin is also important in the cytolytic event that follows adherence (11,12). Zymodeme analysis was employed to discriminate the virulent *E. histolytica* and the nonvirulent *E. dispar*. The analysis indicates that HKX is a key enzyme and that GPI and PGM are also useful. The amino acid sequences of the LecHgl, HKX, GPI, and PGM genes from XLAC were identical to those of the HM1:IMSS strain. This result suggests that the virulence of the XLAC strain is similar to that of the HM1:IMSS strain.

In Japanese amebiasis patients, the crude antigen of the Asian *E. histolytica* strain HK9 generates a higher serum-positive rate than that of the Mexican strain HM1:IMSS (unpublished data). This result suggests that the local *E. histolytica* strain is more suitable for diagnosing amebiasis. No axenic *E. histolytica* strain has been isolated from China in the past years. This study is the first to isolate the *E. histolytica* strain XLAC from Chinese amebic patients. Detailed examination of its virulence may play an important role in further diagnostic studies of Chinese amebiasis.

*E. histolytica* loses its virulence after a long in vitro culture. However, *E. histolytica* can restore its virulence by injecting it into hamster liver (13,14). In the present study, $10^5$ *E. histolytica* trophozoites injected into hamster liver can induce liver abscesses, whereas $5 \times 10^5$ *E. histolytica* trophozoites cannot (data not shown). The rate of erythrocyte ingestion after the injection of XLAC trophozoites was higher than that of the original XLAC strain. The XLAC strain restored its virulence after it was injected into hamster liver. This study can be a good model for studying the virulence changes in *E. histolytica*.
