BioScience Trends is one of a series of peer-reviewed journals of the International Research and Cooperation Association for Bio & Socio-Sciences Advancement (IRCA-BSSA) Group and is published bimonthly by the International Advancement Center for Medicine & Health Research Co., Ltd. (IACMHR Co., Ltd.) and supported by the IRCA-BSSA and Shandong University China-Japan Cooperation Center for Drug Discovery & Screening (SDU-DDSC).

BioScience Trends devotes to publishing the latest and most exciting advances in scientific research. Articles cover fields of life science such as biochemistry, molecular biology, clinical research, public health, medical care system, and social science in order to encourage cooperation and exchange among scientists and clinical researchers.

BioScience Trends publishes Original Articles, Brief Reports, Reviews, Policy Forum articles, Case Reports, News, and Letters on all aspects of the field of life science. All contributions should seek to promote international collaboration.

1. Introduction

Most of life’s activities cannot function properly without ion channels (1). Likewise, many studies have found that tumor proliferation, invasion, and metastasis are always accompanied by changes in ion channels, and particularly changes in the expression of transient receptor potential (TRP) channels. TRP channels are Ca²⁺ entry channels. They are ubiquitously expressed in a wide variety of tissues and have an extraordinarily diverse set of functions. Tumor formation and metastasis are complex processes involving multiple genes and multiple steps, including oncogenesis, basement membrane degradation, matrix permeability, cell adhesion, and vessel formation. During these processes, many genetic alterations induce changes in TRP channels expression, and the abnormal expression of these channels may promote the growth, proliferation, and metastasis of tumor cells (2). A growing amount of evidence from both in vitro and in vivo studies has implicated TRP channels in these processes. For example, TRPM8 is highly expressed in prostate cancer (3) and TRPM7 channels influence the growth and proliferation of head and neck tumor cells (4).

2. TRP

TRP genes were first described in Drosophila melanogaster in studies related to the fruit fly’s visual system, but the genes were not recognized until Montell and Rubin’s work in 1989 (5). As their research progressed, TRP channels were further understood, but the original study did not go far enough. About thirty TRP channels have currently been identified, and they are grouped into seven main superfamily...
subfamilies depending on their homology and channel function: TRPC (canonical), TRPV (vanilloid), TRPM (melastatin), TRPML (mucolipin), TRPP (polycystin), TRPA (ankyrin transmembrane protein), and TRPN (NomPC-like). With the exception of TRPN proteins, the other TRP proteins have been detected in mammals; TRPN proteins have been detected in fruit flies and zebra fish (6,7). According to in silico sequence analysis, all of the TRP proteins contain six transmembrane segments (S1-S6) and a pore-forming loop between segments S5 and S6. The major differences between TRP channel subfamilies are found in the N- and C-terminal cytosolic domains, which contain putative protein interaction and regulatory motifs (8) (Figure 1). Most TRP channels are non-selective cation channels, and they are widely expressed in almost all tissues and cell types. These channels also perform various functions, including taste transduction, temperature sensation, muscle contraction, and cell death (9,10).

3. TRP channels and cancer

TRP channels are increasingly recognized as playing roles in the growth, proliferation, migration, and invasion of cancer cells (Table 1 and Figure 2).

3.1. TRP channels and lung cancer

Of all cancers, lung cancer has the highest mortality rate. It is a major public health problem and causes death worldwide. More than 1.3 million new lung cancer cases and over one million deaths due to lung cancer occur every year (11). In 2013, the US had approximately 228,190 new lung cancer cases and approximately 159,480 deaths due to lung cancer-related disease (12). The median survival time for patients with advanced lung cancer is only 8-12 months (13,14). Invasion, metastasis, and recurrence are common biological characteristics of lung cancer, and they are also the major obstacles hampering therapeutic interventions and prognosis.

Recent studies have implicated TRPC1, TRPC3, TRPC4, TRPC6, TRPM7, and TRPM8 as playing a role in lung cancer.

TRPC1 regulates cell proliferation and migration. In non-small cell lung cancer cell lines, siRNA-mediated TRPC1 depletion inhibits cell proliferation and induces G0/G1 cell cycle arrest, resulting in a dramatic decrease in cell growth. TRPC1 might mediate these processes via epidermal growth factor receptor (EGFR) phosphorylation and the activation of EGF-induced signaling pathways (15). Jiang et al. found that the expression of TRPC1, TRPC3, TRPC4, and TRPC6 was correlated with the grade of NSCLC differentiation; no correlation was observed between TRP channel expression and age, sex, smoking history, or cell type. The blocking of TRPC channels inhibited A549 cell proliferation, while over-expression of TRPCs led to increased proliferation. Additionally, all-trans-retinoic acid (ATRA) induced the up-regulation of TRPC3.

**Ref.**

TRPC4, and TRPC6 expression and enhanced Ca\(^{2+}\) influx in A549 cells (16). Conversely, Saito et al. suggest that TRPC3 expression is related to the progression and the clinicopathological characteristics of lung cancer (17). The 5-year overall survival (OS) and disease-free survival (DFS) rates for patients with higher levels of TRPC3 mRNA expression are significantly higher than the rates for patients with lower levels of TRPC3 mRNA. Higher levels of TRPC3 expression in tumor cells are an independent predictor of a better prognosis for patients with lung adenocarcinoma.

In A549 lung cancer cells, the depletion of TRPM7 expression via RNA interference inhibited cell migration, and TRPM7 is positively correlated with EGF expression (18). TRPM8 is the predominant thermoceptor for cellular and behavioral responses following exposure to cold temperatures (19). This thermoceptor has been studied in different contexts, including breast adenocarcinoma, lung adenocarcinoma, melanoma, and prostate cancer (20).

### 3.2. TRP channels and breast cancer

Breast cancer is the most frequently diagnosed cancer (excluding skin cancers) and has the second highest mortality rate of all cancers, following lung cancer, in the US. An estimated 39,510 deaths were expected to occur in the US in 2012. Notably, the incidence of breast cancer has increased in developing countries; about half of the new breast cancer cases and 60% of breast cancer-associated deaths occur in developing countries (21).

TRPC1, TRPC3, TRPC6, TRPM7, TRPM8, and TRPV6 expression are correlated with breast cancer. Dhenin-Duthille et al. observed high levels of TRPC1, TRPC6, TRPM7, TRPM8, and TRPV6 expression in human breast ductal adenocarcinoma (hBDA) tissue in comparison to adjacent non-tumor tissue. A study reported that TRPC1, TRPM7, and TRPM8 expression are strongly correlated with the Scarff-Bloom-Richardson (SBR) grade, Ki67 proliferation index, and tumor size (22). Moreover, the activation of TRPC1 enhanced the proliferation of MCF-7 cells, a human breast cancer cell line with low metastatic potential, by stimulating phosphorylation of extracellular signal-regulated kinases 1 and 2 (ERK1/2) and Ca\(^{2+}\) entry (23).

Previous studies reported that TRPC3 and TRPC6 are involved in the control of the growth of polarized epithelial cells (24). Recently, TRPC6 was found to be expressed and to be the predominant TRPC channel in biopsied breast cancer tissue, and TRPC3 appears to be significantly up-regulated in breast cancer tissue (25).

The level of TRPV6 expression is higher in invasive tissue compared to corresponding non-invasive tissue and TRPV6 expression has been assessed using laser capture microdissection. TRPV6 silencing can inhibit MDA-MB-231 migration and invasion in addition to MCF-7 cell migration (22). Moreover, limited estrogen receptor (ER) signaling reportedly leads to lower levels of TRPV6 expression, and the antitumor effect of Tamoxifen may be related to the inhibition of TRPV6 expression (26).
TRPM7 plays an important role in breast cancer. TRPM7 is both an ion channel and a protein kinase that is ubiquitously expressed in various tissues; these proteins are also called "channels plus enzymes" or "chanzymes". Studies have found that the TRPM7 channel regulates breast cancer cell proliferation, and TRPM7 is over-expressed in breast carcinoma tissue and is positively correlated with the Ki67 mitosis marker (27). Some studies have found that TRPM7 influences cell adhesion and migration via the regulation of myosin-IIA filament stability and that it influences protein localization by phosphorylating the heavy chain (28). However, one study found that mitogen-activated protein kinase (MAPK) signaling pathways are involved in the TRPM7-mediated migration and invasion of MDA-MB-435 breast cancer cells. Silencing of TRPM7 caused a significant reduction in the migration and invasion potential of MDA-MB-435 breast cancer cells in addition to a decrease in the levels of phosphorylated Src and MAPK (29, 30).

TRPM8 channels are highly expressed at both the mRNA and protein levels in the MCF-7 breast cancer cell line. These channels are over-expressed in breast adenocarcinomas and are correlated with estrogen receptor positive (ER+) tumors according to immunohistochemical analysis (31).

3.3. TRP channels and prostate cancer

Prostate cancer is the second leading cause of internal malignancy in men worldwide, and approximately 29,720 men die from the disease each year in the US (12). Furthermore, data indicate that prostate cancer mortality is increasing in Asia, and particularly in China and Japan (32).

A number of TRP channels have been implicated in prostate cancer, including TRPV1, TRPV2, TRPV6, TRPM8, TRPM2, and TRPC6. Among these, TRPV6 and TRPM8 are the most studied and characterized.

The expression of TRPV6 may be a predictor for prostate cancer progression because levels of TRPV6 mRNA and protein are both substantially elevated in prostate carcinoma compared to normal tissue or cells. Lehen et al. first found that Ca\(^{2+}\) entry via the TRPV6 channel controls proliferation directly and promotes apoptosis resistance in prostate cancer cells (33). TRPV6-targeted siRNA has been reported to effectively inhibit the transcription of TRPV6 mRNA, inhibit the proliferation of human prostate cancer LnCaP cells, arrest the LnCaP cell cycle in the G0 and G1 phases, and induce LnCaP apoptosis (34). Moreover, the expression of TRPV6 in lymph node metastases and androgen-insensitive tumors is markedly and significantly decreased in comparison to untreated tumors. Furthermore, TRPV6 expression is significantly correlated with the Gleason score, the pathological stage, and extraprostatic extensions (35).

Tsaveler et al. originally identified TRPM8 in 2001 by screening a prostate cDNA library; the gene was described as a novel prostate-specific gene with expression that increased during the transformation of prostate cancer (20). In normal prostate cells, there is a slight level of TRPM8 expression. In prostate cancer, however, the expression of TRPM8 increases dramatically (36). A similar result has been reported by Fuessel et al., who analyzed multiple tumor markers in primary prostate cancers via quantitative real-time PCR (37). One potential mechanism for the action of TRPM8 in prostate carcinoma is through the inhibition of the migration of prostate cancer cells by inactivating focal adhesion kinase. Furthermore, the over-expression of TRPM8 is independent of changes in the level of androgen receptor (AR) mRNA expression (38). Henshall et al. found that the expression of TRPM8 decreased markedly following anti-androgen therapy. They also showed that TRPM8 expression decreased when prostate cancer cells became androgen-independent, supporting the hypothesis that TRPM8 is regulated by androgens (39). Indeed, the androgen dependence of TRPM8 expression is related to the stage of differentiation of prostate epithelial cells. Affymetrix gene chip experiments have been conducted to determine whether TRPM8 expression was correlated with the Gleason grade or the TNM stage. Results of those experiments indicated that TRPM8 mRNA expression increases with the Gleason score and TNM stage (40).

TRPC6 is also up-regulated in prostate cancer and is associated with the histological grade, Gleason score, and extra-prostatic cancer extension. However, there is no significant difference between androgen-independent and androgen-dependent tumors (41). In addition, TRPV1 and TRPV2 are up-regulated in patients with metastatic cancer (42-44). Levels of TRPM2 mRNA are elevated in both prostate cancer tissue and in LnCaP and PC3 cell lines (45,46). This suggests that these channels could play an important role in the diagnosis and treatment of prostate carcinoma.

3.4. TRP channels and ovarian cancer

Ovarian cancer (OC) is one of the most common gynecological cancers. It poses a great challenge because it is a heterogeneous, rapidly progressing, and highly lethal group of malignancies (47). According to estimates, approximately 22,240 women will be diagnosed with OC and 14,030 women will die from this disease in 2013 in the US (12). The etiology of OC is still poorly understood.

TRPC1, TRPC3, TRPC4, and TRPC6 channels were identified by Western blotting and immunostaining in human ovarian adenocarcinoma tissue and in ovarian adenocarcinoma-derived SKOV3 cells. In 2009, Yang et al. found that the protein expression of TRPC3 increased markedly in human OC tissue compared to
normal ovarian tissue (48). The down-regulation of TRPC3 expression in SKOV3 cells led to a reduction in proliferation, suppression of epidermal growth factor-induced Ca\(^{2+}\) influx, dephosphorylation of Cdc2 and CaMKIIα, and prolonged M phase progression in these cells. Furthermore, decreased expression of TRPC3 suppressed tumor formation when SKOV3 cells were injected into nude mice. A 2013 study by Zeng et al. reached similar conclusions with RT-PCR, whole-cell patch recording, Western blotting, and immunostaining (49). Additionally, they also found that some spliced variants of TRPC1, TRPC3, TRPC4, and TRPC6 were expressed in ovarian cancer. TRPC channel activity was blocked using 2-APB, SKF-96365, or TRPC isoform-specific functional antibodies or by transfecting cells with TRPC siRNAs; blocking of the channel significantly inhibited cancer cell proliferation. Furthermore, the level of TRPC expression is reportedly correlated with the grade of cancer differentiation, and the over-expression of TRPC genes could also increase ovarian cancer colony growth. An interesting fact is that the expression of TRPC genes in undifferentiated human ovarian cancer is significantly lower than their level in normal ovarian tissue. Further study is required to elucidate the role of TRPC channels in ovarian cancer.

3.5. TRP channels and gastric cancer

Gastric cancer continues to be a leading cause of cancer death worldwide (50). In East Asia, including South Korea, Japan, and China, the morbidity due to gastric cancer is the second highest among common cancers while the mortality due to that cancer is the third highest among common cancers. In more than half of gastric cancer cases, cancer recurs after curative surgery, and the median survival time for these patients is only 6-9 months (51,52). The prognosis for these patients is poor mainly because there are limited diagnostic measures for early detection and because of the clonal hyperplasia that is characteristic of gastric cancer cells. The discovery of TRP channels may help to improve the diagnosis and treatment of gastric cancer.

TRPC6, TRPM7, and TRPV6 are the main TRP channels associated with gastric cancer. TRPC6 is not only associated with lung cancer, breast cancer, prostate cancer, and ovarian cancer as mentioned earlier, but it also over-expressed in gastric cancer epithelial cells compared to normal gastric epithelial cells. When the TRPC6 channel was inhibited with SKF96365, the growth of gastric cancer cells was suppressed and cells were arrested in the G2/M phase. Cai et al. found that the histamine-mediated Ca\(^{2+}\) elevation in MKN45 human gastric cells was inhibited by SKF96365 and DNC6, and that inhibition of TRPC6 suppressed the formation of gastric tumors in nude mice (53).

The activation of TRPM7 is associated with the growth and survival of human gastric adenocarcinoma cells. Kim et al. examined the expression and potential role of TRPM7 channels in the growth and survival of AGS cells, the most commonly used line of human gastric adenocarcinoma cells (54). Abundant expression of TRPM7 messenger RNA and protein were observed in AGS gastric cancer cells. Transfection of AGS cells with TRPM7 siRNA significantly reduced the expression of TRPM7 mRNA and protein levels as well as the amplitude of the TRPM7-like currents. Blocking of TRPM7 channels with La\(^{3+}\) and 2-APB or suppression of TRPM7 expression with siRNA inhibited the growth and survival of these cells. Kim et al. later found that TRPM7 channels are over-expressed in HEK 293 cells undergoing Rg3-induced cell death. Ginsenoside Rg3 inhibits the growth and survival of gastric cancer cells, which occurs due to the blocking of TRPM7 channel activity (55,56).

Moreover, the up-regulation of TRPV6 levels has been observed in gastric cancer cells. Over-expression of TRPV6 in normal cells increased capsaicin-induced apoptosis, and knockdown of TRPV6 in cancer cells suppressed this activity (57).

3.6. TRP channels and liver cancer

Liver cancer (696,000 deaths, 9.2% of all cancer deaths) is the third most common cause of cancer death after lung cancer (1.38 million, 18.2% of all cancer deaths) and gastric cancer (738,000 deaths, 9.7% of all cancer deaths) worldwide (58). There are two common types of cancer affecting the liver, hepatocellular carcinoma (HCC) and liver metastases from colorectal cancer (LM-CRC). Liver cancer greatly impacts people’s health, and this is particularly true in China (approximately 350,000 incident cases per year) (59).

Numerous studies have shown that several TRP channels are present in liver cancer tissue, including TRPC1, TRPC3, TRPC6, TRPV1, TRPV2, TRPV4, TRPM4, and TRPM7. TRPC1, TRPC3, TRPC6, TRPM4, and TRPM7 mRNAs are expressed in both rat hepatocytes and in H4-IIE cells (derived from rat liver tumor cells); immunofluorescence was used to directly compare these cells to hepatocytes isolated from normal rat liver (60). TRPC6 is very weakly expressed in hepatocytes isolated from healthy patients and is expressed at much higher levels in human liver tumor tissue. Overexpressing TRPC6 or silencing TRPC6 via siRNA revealed that increased expression of TRPC6 is associated with increased thapsigargin-initiated Ca\(^{2+}\) entry and an increased rate of cell proliferation (61).

TRPV1 and TRPV4 are reported to be involved in modulating cell migration (62). In addition, high levels of TRPV1 expression have been noted in hepatocarcinoma tissue in comparison to normal liver tissue. Clinicopathologic examination indicated a
significant correlation between TRPV1 expression and histopathologic differentiation. Moreover, univariate analysis revealed that low levels of TRPV1 expression were associated with increased disease-free survival (63).

Quantitative PCR, Western blotting, and immunofluorescence analyses revealed increased levels of TRPV2 mRNA and protein expression in moderately and well-differentiated human hepatocarcinoma tissues compared to poorly differentiated tumors. Clinicopathologic assessment suggested a significant association between TRPV2 expression and portal vein invasion and histopathologic differentiation (64).

3.7. TRP channels and nasopharyngeal carcinoma

Compared to the malignant cancers mentioned earlier, nasopharyngeal carcinoma (NPC) is a rare malignancy in most parts of the world. However, the incidence of NPC is relatively high in Asian countries, and China accounts for almost 80% of all NPC cases. An annual incidence of more than 20 cases per 100,000 has been reported in southern China. Men are twice as likely to develop NPC as women (65). NPC is a confusing, misdiagnosed, and poorly understood disease. Radiotherapy is a primary treatment for nasopharyngeal carcinoma and has significantly improved clinical outcomes. The median survival time for patients receiving radiotherapy is approximately 52 months, and the 5-year survival rate is 50-80% (66, 67). Although many patients with NPC had a good clinical prognosis, some still died of recurrence or metastatic disease. Furthermore, related risk factors play an important role during the development of the tumor type.

TRPM7 warrants mention when considered the relationship between NPC and TRP channels. TRPM7 is a bifunctional protein consisting of a Ca\(^{2+}\) and Mg\(^{2+}\) permeable TRP channel that is fused to a C-terminal \(\alpha\)-kinase domain, and this channel plays an important role in regulating cell adhesion and directional migration. A pro-migratory role of TRPM7 was noted in NPC cells, in which impaired TRPM7 channel function significantly reduced cellular migratory potential. Conversely, increased TRPM7 activity promoted migration. Those researchers used RNAi technology to down-regulate TRPC1 in CNE2 cells. Down-regulation of TRPC1 significantly attenuated the adhesive and invasive abilities of NPC cells (70).

3.8. TRP channels and glioblastoma

Glioblastoma is the most common malignant primary brain tumor, and it accounts for almost 80% of all primary brain tumors. Despite advances in surgical and adjuvant radiation and chemotherapy strategies, glioblastoma continues to be associated with a poor prognosis (71). Patients with glioblastoma multiforme have a median survival of approximately 12 months. Approximately 10,000 new cases are diagnosed each year in the US (72).

Only two factors have thus far been shown to conclusively affect glioma risk: exposure to high doses of ionizing radiation and inherited mutations in highly penetrant genes associated with rare syndromes. Therefore, additional factors that correlate with glioblastoma occurrence and development should be studied (71).

Different studies have suggested that TRP channels (e.g., TRPC1, TRPC3, TRPC4, TRPC5, TRPC6, TRPV1, TRPV2, TRPV4, TRPM2, and TRPM8) are likely to play a role in glioma progression, growth and/or invasion.

The TRPC1 channel is associated with lipid rafts and is essential for glioma chemotaxis in response to stimuli such as epidermal growth factor (EGF). Gliomas are attracted to EGF in a chemotactic manner. Stimulation with EGF results in TRPC1 channel localization at the leading edge of migrating D54MG glioma cells. Chemotaxis toward EGF was lost when TRPC channels were pharmacologically inhibited or...
knocked down with TRPC1-specific shRNA (73).

The TRPC6 channel is involved in the growth of glioblastoma. Some studies suggest that TRPC6 is more abundant at both the protein and mRNA levels in human glioma tissue. The increased expression of TRPC6 is also associated with the grade of glioma malignancy. Inhibition of TRPC6 activity or decreased expression of the channel led to an increase in intracellular Ca\(^{2+}\) via platelet-derived growth factor, which suppressed cell growth and clonogenic ability and induced cell cycle arrest in the G2/M phase (74).

Moreover, TRPV1 has been implicated in the capsaicin-induced apoptosis of glioma cells. TRPV2 negatively controls glioma cell survival and proliferation and protects the cells from Fas-induced apoptosis in an ERK-dependent manner (75,76).

3.9. TRP channels and melanoma

Among skin diseases, malignant melanoma is the leading cause of death and accounts for approximately 75% of deaths attributed to skin disease due to its propensity to metastasize. Localized melanoma is curable by surgical techniques and immunotherapy, whereas there are limited therapeutic options for metastatic melanoma or melanoma with metastatic potential. Once diagnosed with metastatic melanoma, most patients will die from the disease within 2 years (77). Moreover, current diagnostic methods are limited in their ability to diagnose early disease and to accurately predict an individual’s risk of disease progression and outcome (78). Thus, melanoma diagnosis and therapy are great clinical challenges.

TRPM1 (also called melastatin) is known to be involved in melanoma, and TRPM2, TRPM7, TRPM8 (also known as Trp-p8), and TRPV2 also play a role. TRPM1 was first discovered by differential display analysis in the B-16 mouse melanoma cell line. The gene is steadily lost during the progression of primary cutaneous and vertical growth phase melanomas (79). Many studies suggest that the TRPM1 gene is a tumor suppressor. TRPM1 mRNA is partially absent or completely absent in approximately 80% of invasive primary melanomas (78).

In their study involving murine cell lines, Duncan et al. reported that TRPM1 was expressed at high levels in poorly metastatic variants of the B16-F1 melanoma cell line and expressed at very low levels in the highly metastatic B16-F10 melanoma cell line (80).

In similar human melanomas experiments, Deeds et al. examined TRPM1 mRNA expression in nevi, primary melanoma, and melanoma metastases. They found high levels of TRPM1 mRNA in melanocytic nevi, but radioactive in situ hybridization was unable to detect levels of TRPM1 mRNA in melanoma metastases (81). Decreased expression of TRPM1 has been shown to correlate with the melanoma cell transition from a low to a high metastatic phenotype (80). Moreover, TRPM1 mRNA is reported to correlate with patient prognosis. Patients with American Joint Committee on Cancer stage I tumors diffusely expressing TRPM1 mRNA have an 8-year disease-free survival rate of 100% while patients with stage I tumors with no TRPM1 expression have an 8-year disease-free survival rate of 77 ± 15%. Furthermore, patients with stage II disease in which tumors diffusely express TRPM1 mRNA have an 8-year disease-free survival rate of 90 ± 7% while patients with stage II disease with no TRPM1 expression have an 8-year disease-free survival rate of 51 ± 8% (82). Some studies suggest that TRPM1 transcription is regulated by the binding of microphthalmia transcription factor (MITF), which is an essential transcription factor for the development of melanoma. Levels of MITF and TRPM1 mRNA are high in several human melanoma cell lines. Endogenous TRPM1 expression may be regulated by MITF up- or down-regulation, and TRPM1 promoter-driven reporters yielded similar patterns (83).

The TRPM8 channel is expressed in the G-361 human melanoma cell line, and the channel is activated by menthol, a naturally occurring ligand for TRPM8. Menthol-induced activation caused prolonged increases in both the intracellular Ca\(^{2+}\) concentration and the amplitude of the current in melanoma cells. The most interesting finding is that exposure to menthol drastically reduced the survival of melanoma cells (84). TRPV2 mRNA is found in benign astrocyte tissues, and its expression progressively decreased in high-grade glioma tissues as the histological grade increased (76).

Moreover, TRPM2 is cited as a factor that can induce melanoma apoptosis and necrosis, while TRPM7 is regarded as a protector and detoxifier in both melanocyte physiology and in melanoma cells (85,86).

3.10. TRP channels and other cancers

Several TRP channels have been identified in other cancers. For example, TRPC6 has been observed in esophageal carcinomas, and TRPM7 and TRPM8 have been identified in pancreatic adenocarcinoma (PDAC). TRPV1, TRPV3, and TRPV6 have been noted in colon cancer, and TRPC1, TRPC4, TRPC6, and TRPC7 have been observed in renal cell carcinoma.

4. Conclusion

In summary, cancer continues to be a public health problem worldwide. Different TRP channels exist in normal tissues and tumors, and some play important roles in the processes of tumorigenesis, migration, and metastasis. Differences in expression of TRP channels may provide a new basis for tumor diagnosis and might be a new target for cancer therapy. Tumor treatment may become more diverse and more accurate. Although
many studies have examined TRP channels and cancer, this area of research is still in its infancy. Current data are not sufficient to ascertain the specific action of TRP since there are no highly selective inhibitors or agonists of TRP. Not all TRP channels have been investigated, and most of the completed research is still inadequate. An inspiring fact is that associations between TRP proteins and various cancers are still being discovered thanks to rapid advances in molecular biology, genetics, and other disciplines. TRP channels may play an important role in the diagnosis and targeted treatment of tumors.

1. Introduction

Rectal cancer is one of the leading causes of cancer related deaths in the world (1). Over the last two decades, advances in new treatment strategies have contributed significantly to the improvement of the outcome of patients with locally advanced rectal cancer (LARC). Compared with postoperative chemoradiotherapy (CRT), preoperative CRT (pre-CRT) reduced toxicity, improved local recurrence control and disease free survival (2,3). For the true benefits, pre-CRT combined with surgery has been implemented as a standard treatment strategy for patients with LARC (3,4). The pathological complete response (pCR) is associated with a high 5-year overall survival rate and disease-free survival (DFS) rate (5-7), but there is a wide spectrum of responses to preoperative CRT, ranging from none to complete. The variety of tumor responses increased the need to find a useful predictive model for the response to CRT to identify patients who will really benefit from this multimodal treatment. Magnetic resonance imaging (MRI), positron emission tomography-computed tomography (PET-CT), serum carcinoembryogenic antigen (CEA), molecular biomarkers analyzed by immunohistochemistry and gene expression profiling are the most used predictive models in LARC. The majority of predictors have yielded encouraging results, but there is still controversy. Diffusion-weighted MRI may be the best model to detect the dynamic changes of rectal cancer and predict the response at an early stage. Gene expression profiling and single nucleotide polymorphisms hold considerable promise to unveil the underlying complex genetics of response to CRT. Because each parameter has its own inherent shortcomings, combined models may be the future trend to predict the response.

Keywords: Rectal cancer, preoperative chemoradiotherapy, prediction, response

**Summary**

Preoperative chemoradiotherapy (CRT) combined with surgery has become a standard treatment strategy for patients with locally advanced rectal cancer (LARC). The pathological response is an important prognostic factor for LARC. The variety of tumor responses has increased the need to find a useful predictive model for the response to CRT to identify patients who will really benefit from this multimodal treatment. Magnetic resonance imaging (MRI), positron emission tomography-computed tomography (PET-CT), serum carcinoembryogenic antigen (CEA), molecular biomarkers analyzed by immunohistochemistry and gene expression profiling are the most used predictive models in LARC. The majority of predictors have yielded encouraging results, but there is still controversy. Diffusion-weighted MRI may be the best model to detect the dynamic changes of rectal cancer and predict the response at an early stage. Gene expression profiling and single nucleotide polymorphisms hold considerable promise to unveil the underlying complex genetics of response to CRT. Because each parameter has its own inherent shortcomings, combined models may be the future trend to predict the response.

quantitative image analysis. The ADC is related to tissue cellularity, tissue organization, extracellular space tortuosity, tumor proliferation, tumor grade, and tumor necrosis (9-11). With respect to ADC as a quantitative biomarker in rectal cancer, several investigations have reported promising results for the prediction and monitoring of therapeutic responses (10-18) (Table 1).

Concerning the pre-CRT ADC value (ADC-pre) as a predictor for response, Sun et al. observed that the mean ADC-pre value in the T-downstaged group was lower than that in the T-non-downstaged group ($p = 0.013$) (10). Based on the tumor regression grade (TRG), ADC-pre showed a positive predictive value of 42% for pCR and 67% for a good response (GR, pCR, and near-pCR) (11). Lambrecht et al. confirmed a low ADC-pre value was significantly correlated with pCR yielding a sensitivity of 100% and specificity of 86% (12). In a recent study, ADC for predicting response was confirmed using the area under the receiver-operating characteristic (ROC) curve analysis with a sensitivity of 75% and specificity of 48% (13). Despite the promising results, there is no consensus whether low ADC-pre value should be used as a predictor for response to CRT because in some studies the ADC-pre value could not reliably discriminate CR from non-CR (14,15). Therefore, relying on ADC-pre seems to be insufficient to select in advance poor responders who might need to undergo early surgery.

Regarding the post-CRT ADC value (ADC-post) as a predictor for response, several studies showed that it could differentiate patients with pCR from those without (14,15,17). Moreover ADC-post value measurements are reliable and reproducible (17). It might be used as a non-invasive tool to evaluate response to CRT as an ADC-post value presenting good performance to select good responders.

The percentage change in the ADC ($\Delta$ADC) was also a useful predictor for pCR. Sun et al. observed that the $\Delta$ADC was significantly higher in the T-downstaged group than that in the nondownstaged group ($p < 0.001$) (10). An increase of ADC had a high positive predictive value for pCR (11,15). During treatment, the mean percentage of ADC increase was significantly greater in the responders than nonresponders ($p < 0.0001$) and a $> 23$% ADC increase had a negative predictive value of 96.3% for TRG4 (18). For dynamic observation $\Delta$ADC during ($\Delta$ADC-during) and after CRT ($\Delta$ADC-post) showed a significantly higher value in patients

with pCR than those without, yielding a sensitivity and specificity of 100% for the ΔADC-during and, respectively, 100% and 93% for the ΔADC-post (12).

With its great development, MRI has potential to assess and predict the response to pre-CRT. First, most studies provided promising results to confirm the predictive value with high sensitivity and specificity. Second, tumors appear hypointense on ADC maps for the diffusion restriction of proton motion which can help differentiate tumorous lesions from non-tumorous lesions such as radiation-induced fibrosis and inflammation. Furthermore, MRI is known to enable the most accurate and useful assessment of tumor (T) staging before CRT (19). So it is convenient to acquire an ADC value. Despite some inconsistent results, ADC values hold great potentiality to be a useful predictor for response. However, all previous studies suffer the same issue that the sample size was too small and lack of standardization in ADC acquisition. Therefore, before ADC can be used as a predictor clinically, large cohort studies are needed.

2.2. Positron emission tomography-computed tomography (PET-CT)

PET-CT has become increasingly used for staging and evaluating therapeutic response in oncology (20). Over the past decades, lots of studies have implemented PET-CT to assess the response to CRT in LARC. Various PET-CT parameters have been investigated: mean standardized uptake value (SUVmean), maximum SUV (SUVmax), Δ SUVmax (SUVmax-pre – SUVmax-post), response index [RI, (SUV_{pre}– SUV_{post})/SUV_{pre}], metabolic tumor volume (MTV), Δ MTV% (MTV_{pre} – MTV_{post})/MTV_{pre}, total lesion glycolysis (TLG, SUVmean × MTV) (Table 2) (19-32). These studies were able to establish a correlation between PET-CT results and CRT response (22-30). Most studies used several parameters but found just one or two parameters correlated with CRT response (21-27). Kim et al. used SUVmax-pre, SUVmax-post, Δ SUVmax and RI to assess tumor response. Univariate and multivariate analysis revealed

SUV: standardized uptake value; CRT: chemoradiotherapy; LARC: locally advanced rectal cancer; pCR: pathological complete response; SUVmean: mean SUV; SUVmax: maximum SUV; SUVmean-post: SUVmean of post CRT; SUVmax-post: SUVmax of post CRT; Δ SUVmax: SUVmax-pre-SUVmax-post; RI: response index (SUV_{pre} – SUV_{post})/SUV_{pre}; MTV: metabolic tumor volume; Δ MTV% (MTV_{pre} – MTV_{post})/MTV_{pre}; TLG: total lesion glycolysis (SUVmean × MTV); VRA: visual response assessment; %Δ SUVmax: the percentage differences (%Δ) between SUVmax-pre and SUVmax-post; %Δ SUVmean: the percentage differences (%Δ) between SUVmax-pre and SUVmax-post.
SUVmax-post was a significant factor for prediction of downstaging and pCR (28). Maffione et al. used 8 parameters to predict TRG and found SUVmax, MTV, TLG-post, RI, ΔMTV%, and ΔTLG% were significantly correlated with pathological treatment response \((p < 0.01)\) while SUVmax-post had the highest sensitivity in predicting TRG (29). SUVmax is the most commonly studied metabolic parameter for semiquantitative analysis of glucose metabolism with PET-CT. However, SUV can be influenced by the nuclear medicine physicians and acquisition protocols, the reproducibility was poorer than those of RI and the percentage differences. Two studies revealed the mean RI was significantly higher in responders than in nonresponders and concluded that RI may be best for assessing the CRT response (25,27). A meta-analysis derived a threshold for RI of 36-52% for predicting response to CRT with a sensitivity and specificity of 86% and 80%, respectively. In the subgroup analysis, the accuracy of the group that underwent PET during therapy (sensitivity 86% and specificity 80%) was statistically higher than that acquired after completion of the therapy (sensitivity 78% and specificity 62%) (31). Everaert et al. investigated the potential value of sequential PET in assessing the response to radiation therapy (RT). The percentage differences between pre- and post-RT scans in SUVmax (%ΔSUVmax), SUVmean (%ΔSUVmax), %ΔMV, and total glycolytic volume (%ΔtGV) were calculated. Significant differences in %ΔSUVmax and %ΔSUVmean were observed between responders and nonresponders (32). However, it remains to be investigated whether these results obtained from patients treated with preoperative RT can be extrapolated to CRT.

Over the past decades lots of PET-CT parameters have been implemented to assess the CRT response in LARC. RI might be the best parameter for response assessment, especially acquired during therapy (25-27). The percentage differences in SUV between pre- and post-CRT, especially %ΔSUVmean, can be considered as valuable markers and worth further study (32). However, it cannot meet clinical use because of its own limitations. First, up to now the results of the predicting value of PET-CT are still not uniform. Second, PET-CT scans were not successful in determining nodal status (24). Third, PET-CT has difficulty in distinguishing between residual cancer and intraluminal or physiologic mucosal activity uptake (30). Fourth, the specificity of predictive value is too low to justify modification of the standard treatment protocol for an individual patient.

3. Serum carcinoembryonic antigen (CEA)

Carcinoembryonic antigen (CEA) is the most widely used tumor marker in patients with rectal cancer. Compared with other potential predictive markers, measurement of serum CEA levels are inexpensive, standardized, widely used and easily performed (33). In recent years, many studies have focused on the predictive value of CEA levels in patients with rectal cancer receiving pre-CRT (Table 3) (34–40). Most studies showed low pre-CRT CEA (CEA-pre) levels with different cut-off values associated with good tumor response or pCR (34–36), but concerning the CEA-pre

predictive values, the results were controversial. Perez et al. didn’t find a correlation between initial CEA-pre level and pCR (37).

Recent studies confirmed the predictive value of post-CRT CEA (CEA-post) levels for response to CRT (37-39). Perez et al. reported that a CEA-post level < 5 ng/mL was associated with increased rates of clinical CR and pCR (37). CEA-post with a different cut-off value of 2.7 ng/mL was also proved to be an independent predictor of good tumor regression (p = 0.001) (38). In a recent study, CEA-post < 2.61 ng/mL also showed a strong predictive value for pCR with a sensitivity of 76.0% and specificity of 58.4% in patients with a low CEA-pre level or in patients with a high CEA-pre level but normalized CEA-post levels (39).

CEA-change as a predictor was first evaluated in a retrospective study, they found patients with a lower CEA-pre level or higher CEA-pre level but CEA reduction ratio ≥ 70% would have a better 5-year DFS. However, it was unknown whether this ratio was related to pCR or not (40). To make sure that the CEA ratio (defined as CEA-post divided by CEA-pre) could be used as a predictor for pCR, Yang et al. found that when CEA-pre levels ≥ 6 ng/mL, the CEA ratio was a significant predictor for pCR, and the optimal cutoff value of CEA ratio was 0.22 with a sensitivity of 87.5% and specificity of 76.7% (39).

Compared with other potential prognostic and predictive markers, measurement of serum CEA levels is inexpensive, widely used and easily performed. There is controversy if CEA-pre could be a predictive marker for pCR or not (34-39). CEA change groups were relevant to pCR, but may not be significant enough (37,38). CEA-post was an independent predictor for response to CRT (37-39), but different studies used different cut-off values and most studies did not mention the sensitivity and specificity of CEA-post as a predictor for CRT response.

4. Molecular markers

Many molecular markers were assessed for response prediction to CRT by immunohistochemistry (IHC) or direct gene sequencing analysis. Recent studies are listed in Table 4.

4.1. p53

Several studies assessed the ability of p53 status to predict response to CRT (41-45). Of these, some studies found that p53 could significantly predict response (43-45). In contrast, with similar sample size and pathological endpoints, some studies found no association between over-expression of the p53 protein and treatment response (41,45). Interestingly, one study found p53 genotype but not a p53 IHC result could predict response to preoperative short-term radiotherapy in rectal cancer (42). A meta-analysis found the wild-type p53 gene was significantly associated with complete response (p = 0.003), and low expression of p53 protein was not significantly associated with complete response (p = 0.124) (46). Due to inconsistencies in different studies, p53 still cannot be considered a reliable predictor for treatment modalities.

4.2. p21

P21 protein has been studied as a response predictor because of the disruption of regulatory networks, in particular those involved in cell death signaling, which may be a causative factor of resistance to radiotherapy (44). Rau et al. reported that lower p21 expression in pre-treatment biopsies was correlated with poor response (47). Another study found p21 and apoptosis together with histologic changes on biopsy specimens obtained 7 days after starting CRT were strong predictors for response to CRT (48).

4.3. K-ras

K-ras plays an important role in colorectal carcinogenesis. Luna-Perez et al. analyzed codons 12, 13, and 61 of K-ras and found that tumors with wild-type K-ras were more likely to be responsive than tumors with mutant K-ras (49). In contrast, in two retrospective studies the K-ras mutation status was not found to be correlated with response or TRG (50,51).

4.4. Epidermal growth factor receptor (EGFR) and vascular endothelial growth factor (VEGF)

EGFR expression is an indicator of poor response to CRT in LARC (52). Kim et al. found a low level of EGFR expression may be a significant predictive molecular marker for increased tumor downstaging after CRT (53). Opposite to the former studies, Zlobec et al. found EGFR-positive tumors were six times more likely to undergo pCR compared with EGFR-negative cases (54). The conflicting results among different studies might be due to IHC methodological differences and heterogeneity of EGFR expression. Those shortcomings may be overcome by gene polymorphism. The most common single nucleotide polymorphism is Sp1 -216 G/T polymorphism in the EGFR promoter region. Evaluating for EGFR Sp1 -216 G/T polymorphism from blood samples and EGFR expression on primary tumor biopsies simultaneously, the major response rate in patients with Sp1 -216 T containing variants is significantly higher in Sp1 -216 GG homozygote patients, but in regard to EGFR expression by IHC no correlation was observed with response rates (55). Low VEGF expression levels also indicated a good pathological response (56). Zlobec et

CRT: chemoradiotherapy; LARC: locally advanced rectal cancer; pCR: pathological complete response; GE: gene expression; IHC: immunohistochemistry; PCR: polymerase chain reaction; TRG: tumor regression grade; EGFR: Epidermal growth factor receptor; VEGF: vascular endothelial growth factor; SNP: single nucleotide polymorphisms; HIF-1α: hypoxia-inducible factor 1α; GLUT-1: glucose transporter-1
al. applied ROC curve derived cut-off scores to VEGF and confirmed VEGF negative tumors were four times more likely to undergo complete tumor regression (54). Despite different results, EGFR or VEGF, especially EGFR Sp1-216G/T polymorphism or VEGF, have yielded disappointing results. No specific molecular marker has yet been proven to be a definitive predictor of the response to CRT. The failure of IHC methods as a means of biomarker discovery is that this assesses small numbers of pre-defined protein markers per tissue section.

5. Gene expression profiling

Instead of focusing on specific factors, recent advances in deoxyribonucleic acid (DNA) microarray-based gene expression profiling technology make it possible to analyze a large number of genes simultaneously, and search systematically for molecular markers to predict responses and outcomes (64). Consequently, several investigators have used gene expression profiling to analyze the genetics of rectal cancer and their predictive potential in terms of response to CRT (Table 5). Ghadimi et al. used two different microarray platforms to analyze pretreatment biopsies and identified 54 genes that were significantly differentially expressed between responders and non-responders based on T-down-staging. The genes were able to predict tumor behavior correctly in 83% of patients (65). Using an Affymetrix U95Av2 Gene Chip, 33 novel discriminating genes related to transcription, cell growth, signal transduction and apoptosis were identified based on TRG in another study. Among the 33 genes, 20 genes expression increased and 13 genes expression decreased in responders as compared to non-responders (66). In the following studies, differentially expressed genes related to cell cycle and/or cell signaling were also successfully identified between responders and non-responders (67-69). The model based on the identified genes predicted multiple markers. A limited number of promising markers have been identified, including p53, p21, EGFR, VEGF, CD133, HIF-1α and so forth. The majority of markers assessed, however, have yielded disappointing results. No specific molecular marker has yet been proven to be a definitive predictor of the response to CRT. The failure of IHC methods as a means of biomarker discovery is that this assesses small numbers of pre-defined protein markers per tissue section.

4.5. Cancer stem cell markers

CD133, CD44, and CD24 have been described as cancer stem cell markers. Several studies confirmed elevated CD133 expression was associated with resistance to CRT in LARC (57-60). The status of CD24 was also found to be significantly associated with response to CRT (p = 0.029) (58). Huh et al. revealed that among 13 molecular markers, only elevated CD44 mRNA levels in pretreatment biopsies might be predictive of poor tumor regression and CD133 level had no significant correlation with the response to CRT (45).

4.6. Markers of tumor hypoxia

Tumor hypoxia can lead to resistance to radiation and chemotherapy by depriving cells of oxygen essential for the cytotoxic activities of these agents (61). Hypoxia-inducible factor 1α (HIF-1α) and glucose transporter-1 (GLUT-1) are intrinsic markers of tumor hypoxia. It has been considered that HIF-1α and GLUT-1 expression may be predictors for poor response. Different from the hypothesis, the HIF-1α and GLUT-1 expressions had no predictive value regarding response to CRT based on TRG in a study carried by Havelund et al. (62). Shioya et al. detected HIF-1α expression in 42.0% of samples but found no significant correlation between the HIF-1α-expression and pathological response (63).

Among molecular markers based on tumor tissues, the vast majority of studies have assessed single or multiple markers. A limited number of promising markers have been identified, including p53, p21, EGFR, VEGF, CD133, HIF-1α and so forth. The majority of markers assessed, however, have yielded disappointing results. No specific molecular marker has yet been proven to be a definitive predictor of the response to CRT. The failure of IHC methods as a means of biomarker discovery is that this assesses small numbers of pre-defined protein markers per tissue section.

CRT: chemoradiotherapy; LARC: locally advanced rectal cancer; CR: complete response.
the response to CRT at an accuracy of over 80% (65-68).

It seems reasonable to apply microarray gene profiling to identify novel molecular markers to predict response to CRT. Each study generated gene expression classifiers capable of high predictive accuracy (65-68), but the use of this microarray data in clinical practice is still limited for several reasons. First, microarray profiling relies on the prompt collection of fresh tissue samples and tumor biopsies consist of varying amounts of stroma, blood vessels and lymphocytes which contribute to the gene expression profiles and thus introduce a potential source of error. Second, the previously reported gene signatures differed considerably in terms of gene composition among different studies which make it difficult to compare the effectiveness of different genes. Third, the numbers of patients in each study were relatively limited. The current reported genes analyzed by microarray technology are not robust enough for clinical utility at this point. However, considering the promising data and usefulness of gene profiling in breast and lung cancer, gene expression profiling holds considerable promise to unveil the underlying complex genetics of response to CRT of rectal cancer if candidate genes are carefully validated in the future.

6. Thymidylate synthase (TYMS)

TYMS is an essential enzyme for cell proliferation and DNA synthesis (70). TYMS is considered the indirect target of 5-fluorouracil (5-Fu) and it was evaluated in several studies as a predictor of response to 5-Fu based pre-CRT in LARC (71-76), but there is much debate about the results. Saw et al. (71) observed that pretreatment biopsy specimens negative for TYMS were predictive of tumor down-staging in the CRT group but not in the radiotherapy group. In a contrasting study, patients with high TYMS IHC staining were more likely to achieve complete and partial response in the CRT group only (72). Even no correlation between TYMS expression and treatment response was observed in a study carried by Bertolini et al. (73). All the above studies used the IHC method to determine the TYMS levels, and limitations of IHC (heterogeneity in the TS assay and classification criteria) may contribute partly to the conflicting results. A genetic approach was used to quantify different TYMS genotype activities (2R/2R, 2R/3R, and 3R/3R). By evaluating the number of tandem repeats of the TYMS gene, patients with either 2R/2R, 2R/3R are more likely to achieve downstaging and pCR than patients with 3R/3R (74). According to 2R/3R and 3R/3R tandem repeat polymorphisms in the TYMS gene, TYMS polymorphisms were classified into a low expression group (2R/2R, 2R/3RC, or 3RC/3RC) and high expression group (2R/3RG, 3RC/3RG, or 3RG/3RG) but no correlation was found between TYMS SNPs and tumor response (75, 76). However, in a further study, patients in the low-expression group with a G>C SNP exhibited a significantly greater tumor downsating rate \((p = 0.001)\) (76). The TYMS gene is complicated and regulation is still not fully understood. The underlying reason for previous contradictory results according to TYMS polymorphisms on the clinical response need to be investigated, and additional novel polymorphisms might be identified to understand the complete role of TYMS genotyping for predicting a 5-Fu based pre-CRT response in rectal cancer.

7. Single-nucleotide polymorphism (SNP) markers

SNP analysis has been used to tailor special gene sites to predict response to CRT (55,75,76). Instead of focusing on specific genes, genome-wide association studies were capable of genotyping thousands of SNPs. It is theoretically possible to identify SNP markers predicting a response to pre-CRT in LARC. A quite recent study has implemented a human 3-step genome-wide SNP strategy for the determination of CRT sensitivity in LARC. In the first step, the screening group was performed using the Genome-Wide Human SNP Array with 906,600 probes in 43 patients with LARC. Then the results of the genotyping analysis were associated with the responses to pre-CRT. USP20rs227450, FAM101Ars795574, ZNF281rs424414, OR2T4rs153870, SLC1A0Ars7rs41398848, CORO2Ars198585, ASZ1rs7808424 MED4rs157125, and CDC42BPArs192986 were identified as CRT-responsive SNPs. In the second step, the above nine candidate SNPs were genotyped by pyrosequencing for clinical validation in a total of 113 patients. The patients carrying the reference allele(C) of the SNP CORO2A rs1985859 were more likely to obtain a positive response (TRG1-3) than the substitution allele (T) \((p = 0.01)\). This was confirmed by the in vitro assay of ionizing radiation cytotoxicity and the clonogenic assay in the third step. However, there are controversial findings with respect to FAM101A, no specific genotype or allelotype showing significant CRT sensitivity was identified in the clinical association study, but downregulation of FAM101A reduced early apoptosis, enhanced colony formation and increased cell survival or viability in RKO cells (77). Despite the controversial findings in the current study and poor concordance between GWA studies, the finding is novel and SNPs are worth further study.

8. Dynamic analyzing

Increasing evidence shows that the way in which tumors respond to radiation is dynamic by analyzing sequential core biopsies (78,79). Recently, the same studies were carried out on rectal cancer. Based on biopsies taken before CRT, after 2, 4, and 6 weeks of CRT and in specimens from the operation, decreasing expressions
of HIF-1α, Bcl-2 and Ki-67 were observed during CRT, but unfortunately no association was seen between the fluctuations of any of the markers and response to CRT (80). In another study, based on biopsy specimens obtained 7 days after starting CRT, the expressions of p21 and apoptosis have been proven to be strong predictors of the response to CRT in rectal cancer (48). Gene expression changes detected on biopsies after a dose of 7.2 Gy at a median time of 1 hour following irradiation found 31 genes significantly up-regulated and 6 genes down-regulated (81). This potentially means that the response may be more accurately predicted after initial treatment cycles rather than only before or after treatment of tissues, but performing serial biopsies is an invasive and unpleasant procedure and has the risk of increasing toxicity from repeated biopsies. As such, a non-invasive means of monitoring early-stage responses would be beneficial. DW-MRI, PET-CT and CEA can detect dynamic changes of rectal cancer during CRT easily and non-invasively. However, the price of PET-CT testing is so high that many patients are unable to afford repeating PET-CT tests and the serum CEA levels of parts of patients are always at a normal level so that CEA detection has no use for them at all. A study including twenty patients underwent MRI before CRT, after 10-15 fractions and 1 to 2 weeks before surgery showed ΔADC-during had a significantly higher value in patients with pCR compared with patients without (12). Due to the above evidences, DW-MRI may be the best model to detect the dynamic change of rectal cancer and predict the response at an early stage.

9. Dual or more models combined

As each parameter has its own inherent shortcomings, a combination of dual or more models may improve the accuracy of a response prediction. A prospective study investigated the combination of PET-CT and DW-MRI for the prediction of a pathological response. Twenty two patients had PET-CT before CRT, after 10 to 12 fractions of CRT, 5 weeks after CRT and had DW-MRI before CRT. Both during and after CRT, the number of false positive results were decreased and consequently specificity was increased by the combination of ΔSUV max and ADC. During CRT the combination of ΔSUVmax > 40% and ADC-pre < 1.06 × 10 mm²/s can predict pCR with a sensitivity of 100% and specificity of 94%. Also, the combination of the provided threshold for ΔSUV max after CRT and ADC-pre was able to predict the response in all 22 patients (82). In a recently published study, the predictive value of PET-CT and CEA was simultaneously evaluated in terms of downstaging and pCR. SUV-post < 3.7 and CEA-pre < 5.3 ng/mL are independent predictors for response to CRT in univariate and multivariate analysis. The combination of SUV-post < 3.7 and CEA-pre < 5.3 ng/mL increased the specificity from 63.6% and 81.8% to 91.6% for pCR (29).

Despite the small number of patients in the studies, the combination of two modalities provide us with complementary information of the tumor and yielded higher accuracy and specificity than the individual investigations, which holds great potential for response prediction. The integration of functional imaging, CEA, together with the numerous potential molecular markers and identified genes will provide us with a bulk of information on each individual patient and make individualized treatment therapy possible. Combined models may be the future trend to predict a response.

10. Conclusion and prospects

The high level of variation in response to CRT and the potentially toxic side effects increased the need for better patient selection in LARC. A major focus of rectal cancer research has been the identification of predictive factors allowing clinicians to predict responses. However, to be able to base treatment decisions, prediction should be effective and applicable in current clinical practice. From the update of current status, prediction is still in its infancy: First, there is still controversy between different results. Second, until now virtually all biomarkers have been identified in retrospective studies and predictions were not effective enough. Third, the number of patients is naturally limited. Fourth, there is the problem of high dimensionality of the therapy regimens: long or short term radiation and different chemotherapy regimens. Fifth, the histopathological evaluation of tumor response is different, such as complete response, partial response, TRG and downstaging. Differences among studies make a direct comparison of the results impossible. So before any predictor is used clinically, tumor response evaluation should be standardized and large consistent cohort studies are needed.

In this review, we have provided an overview of the different predictive models. The ADC of MRI, SUV of PET-CT, CEA, gene expression profiling and SNPs analysis are the most potential predictors for response to CRT from the evidence today. Due to the evidence that the way in which tumors respond to radiation is dynamic, DW-MRI may be the best model to detect the dynamic change of rectal cancer and predict the response at early stage. Considering the promising data and usefulness of gene profiling in other cancers, gene expression profiling and SNPs analysis hold considerable promise to unveil the underlying complex genetics of response to CRT in rectal cancer. As each parameter has its own inherent shortcomings and a combination of dual or more models may provide us with complementary information, combined models may be the future trend to predict a response. Before any predictor is used clinically, large consistent cohort studies are needed.

Summary

T-antigen (Galβ1-3GalNAcα-1-Ser/Thr) is an oncofetal antigen that is commonly expressed as a carbohydrate determinant in many adenocarcinomas. Since it is associated with tumor progression and metastasis, production of recombinant antibodies specific for T-antigen could lead to the development of cancer diagnostics and therapeutics. Previously, we isolated and characterized 11 anti-T-antigen phage clones from a phage library displaying human single-chain antibodies (scFvs) and purified one scFv protein, 1G11. More recently, we purified and characterized 1E8 scFv protein using a Drosophila S2 expression system. In the current study, four anti-T-antigen scFv genes belonging to Groups 1-4 were purified from inclusion bodies expressed in Escherichia coli cells. Inclusion bodies isolated from E. coli cells were denatured in 3.5 M Gdn-HCl. Solubilized His-tagged scFv proteins were purified using Ni²⁺-Sepharose column chromatography in the presence of 3.5 M Gdn-HCl. Purified scFv proteins were refolded according to a previously published method of step-wise dialysis. Two anti-T-antigen scFv proteins, 1E6 and 1E8 that belong to Groups 1 and 2, respectively, were produced in sufficient amounts, thus allowing further characterization of their binding activity with T-antigen. Specificity and affinity constants determined using enzyme-linked immunosorbent assay (ELISA) and surface plasmon resonance (SPR), respectively, provided evidence that both 1E8 and 1E6 scFv proteins are T-antigen specific and suggested that 1E8 scFv protein has a higher affinity for T-antigen than 1E6 scFv protein.

Keywords: T-antigen, ScFv, phage display, anti-carbohydrate antibodies, inclusion bodies

1. Introduction

Antibodies are a modular defense system that identifies and neutralizes foreign objects such as bacteria and viruses. Each antibody recognizes a specific, unique target antigen that binds at the antibody's antigen-binding site. This binding mechanism allows an antibody to tag a microbe and an infected cell to be attacked by other parts of the immune system as well as to directly neutralize its target. Antibodies contain variable domains characterized by structurally hypervariable regions, also known as complementarity determining regions (CDRs). The variable-region fragment (Fv fragment) is the smallest unit of an immunoglobulin molecule with functional antigen-binding activity. A single-chain variable fragment (scFv) consists of variable regions in the form of a heavy chain (VH) and a light chain (VL) that are joined by a flexible peptide linker and that are readily expressed in E. coli (1).

Alterations in cell surface carbohydrates are commonly found in cancerous tissues (2). T-antigen (Galβ1-3GalNAcα-1-Ser/Thr), also known as Thomsen-Friedenreich antigen (TF antigen), is an oncofetal antigen. It is commonly expressed as carbohydrate determinants of many adenocarcinomas and is also associated with tumor progression and metastasis (3-5). The availability of human antibodies against T-antigen would thus greatly facilitate the development of cancer diagnostics as well as cancer therapeutics.

In the authors' laboratory, phage display technology has been used to obtain scFv genes with specificities for carbohydrate moieties since many carbohydrates are self-antigens that seldom induce an immune response in animals (6,7). Genes encoding anti-Man3, anti-Lewis X,
anti-Tn-antigen, and anti-T-antigen scFv proteins have been isolated from a phage library displaying human scFvs that had been characterized after purification of scFv proteins expressed in different expression systems (8-12).

*Escherichia coli* expression systems are the most prevalent systems for production of recombinant proteins (13,14). Efficient microbial production systems have allowed the production of heterologous proteins in sufficient amounts for diagnostic and therapeutic purposes as well as for structural studies (15-18). When heterologous proteins were highly expressed in *E. coli*, however, the proteins tended to form inclusion bodies in the cytoplasm. Purification of recombinant proteins from inclusion bodies requires refolding processes that are rather tedious, although the current authors recently reported purification and characterization of scFv proteins (19,20).

Previously, 11 anti-T-antigen phage clones were isolated from a phage library and categorized into four groups using a glycolipid, Galβ1-3GalNAcα-hexaethylene glycol-3,5-bis-8-dodecylxy benzamide (T-antigen E6-BDB) (II). Of those, Group 4 scFv protein (1G11) was expressed in *E. coli* from its phagemid and purified to near homogeneity (II). However, the level of expression of the 1G11 scFv protein in *E. coli* was not sufficient for further characterization. More recently, a Group 1 1E8 scFv protein was successfully expressed and purified in a *Drosophila* S2 expression system (21). To compare scFv proteins belonging to Groups 1-4, the current study expressed and purified four different types of anti-T-antigen scFv genes using an *E. coli* expression system. Of four scFv proteins purified, levels of expression of 1E6 and 1E8 scFv proteins were high enough for characterization of their binding specificity and affinity for T-antigen. Enzyme-linked immunosorbent assay (ELISA) and surface plasmon resonance (SPR) analyses confirmed the binding activity of both scFv proteins to various T-antigen-presenting conjugates. Affinity constants determined using SPR suggested that 1E8 scFv protein bound to T-antigen with one-order higher affinity than 1E6 scFv protein. These results may provide a basis for the future development of cancer diagnostics and therapeutics.

2. Materials and Methods

2.1. Materials

*E. coli* strain BL21(DE3), Benzonase®, Nuclease, and the pET22b(+) expression vector were obtained from Novagen (Germany). The vector was modified to encode the pelB leader and His-tag at the C-termini. *E. coli* strain JM109 was obtained from TaKaRa BIO (Shiga, Japan). Bovine serum albumin (BSA), human immunoglobulin G (IgG), Trizma base, guanidine hydrochloride (Gdn-HCl), tween 20, oxidized L-glutathione (GSSG), reduced L-glutathione (GSH), lysozyme, and 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES) were purchased from Sigma-Aldrich (St Louis, MO, USA). The synthesis of neoglycolipids including T-antigen E6-BDB was previously described (11). Human serum albumin (HSA)-conjugated T-antigen was purchased from Glyco Tech (Gaithersburg, MD, USA). Ni²⁺-Sepharose 6 Fast Flow, and SA sensor chips, and an amine coupling kit were obtained from GE Healthcare (Uppsala, Sweden). ABTS reagent was obtained from Roche Diagnostics K.K. (Basel, Switzerland). B-PER® reagent and His Probe-HRP were obtained from Thermo Fisher Scientific Inc. (Waltham, MA, USA). Anti His-tag mouse monoclonal antibody was purchased from Abcam (Cambridge, MA, USA). Dithiothreitol (DTT), L(+) arginine, carbenicillin, isopropyl-β-D-thiogalactopyranoside (IPTG), and other chemicals were obtained from Wako Pure Chemical Industries (Osaka, Japan).

2.2. Anti-T-antigen scFv-genes

Anti-T-antigen scFv clones were obtained using a neoglycolipid, Galβ1-3GalNAcα-hexaethylene glycol-3,5-bis-8-dodecylxy benzamide (T-antigen E6-BDB), as a probe from a phage library by panning and screening as previously described (II). Eleven phage clones were isolated and characterized using DNA sequencing and ELISA, which revealed four groups of clones with T-antigen binding activity. In this study, 1E8, 1E6, 1E10, and 1G11 scFv genes were selected as respective representatives of Groups 1, 2, 3, and 4 (II).

2.3. Construction of scFv expression vectors for *E. coli*

Four anti-T-antigen scFv genes, 1E8, 1E6, 1E10, and 1G11, were amplified by PCR from phagemids encoding respective scFv genes (II) as templates using corresponding sets of Fw and Rv primers as listed in Table 1. 1E8, 1E6, 1E10, and 1G11 scFv genes were ligated into *Bam*HI-*Not*I-digested pET22b to construct pET22b/1E8, pET22b/1E6, pET22b/1E10, and pET22b/1G11 expression vectors, respectively. *E. coli* JM109 and BL21(DE3) were used as host cells for plasmid preparation and expression of scFv proteins, respectively. The scFv sequences of pET22b/1E8, pET22b/1E6, pET22b/1E10, and pET22b/1G11 were confirmed by DNA sequencing.

2.4. Expression, purification, and refolding of scFv proteins in *E. coli* BL21(DE3)

*E. coli* BL21(DE3) cells transformed with pET22b/1E8, pET22b/1E6, pET22b/1E10, and pET22b/1G11 expression vectors were seeded into 60 mL of LB medium containing 50 µg/mL carbenicillin. After cells were grown to OD600 of ~0.5 by incubation at 37°C
with shaking, expression of scFv proteins was induced by the addition of 1 mM IPTG. Bacterial cells were incubated for 4 h and then harvested by centrifugation at 2,900× g for 30 min, after which they were stored at -30°C for future experiments. Inclusion bodies were prepared from the bacterial cells by suspension in B-per Bacterial Protein Extraction Reagent according to the manufacturer’s protocol. Briefly, 2.5 mL of the reagent containing 500 µg of lysozyme and 63 U of benzonase per g of wet cells was added to bacterial cells. After the mixture was gently shaken for 10 min, pellets were collected by centrifugation at 14,500× g for 20 min and these were then resuspended in 15 mL of 10-fold diluted B-per reagent. After the mixture was gently shaken for 10 min, pellets were collected as inclusion bodies by centrifugation at 14,500 g for 20 min.

Inclusion bodies were solubilized in 20 mM sodium phosphate buffer, pH 7.4, containing 3.5 M Gdn-HCl and 0.2 M NaCl (3.5 M Gdn-HCl buffer), and centrifuged at 14,500× g for 30 min. Ni²⁺-Sepharose slurry (0.5 mL) was added to test tubes containing the supernatant. After the tubes were inverted overnight at 25°C, the Ni²⁺-Sepharose slurry was packed into columns. The columns were washed thoroughly with 3.5 M Gdn-HCl buffer containing 40 mM imidazole. ScFv proteins were then eluted with 3.5 M Gdn-HCl buffer containing 500 mM imidazole and 5 mM DTT. The eluted proteins were refolded as described below according to the method previously described (16) with some modifications. The scFv proteins purified in the presence of 3.5 M Gdn-HCl were refolded by stepwise dialyses as follows. The concentrations of the affinity-purified denatured scFv proteins were adjusted to 3.3 mM in 3.5 M Gdn-HCl buffer. The denatured scFv proteins in 20 mL were dialyzed against 300 mL of 50 mM Tris-HCl buffer, pH 8.0, containing 0.2 M NaCl and 1 mM EDTA (dialysis buffer) in the presence of 2 M Gdn-HCl, and then stepwise dialysis was done against (i) 80 mL of the dialysis buffer containing 1 M Gdn-HCl, 0.4 M L-arginine, 1 mM GSSG, and 2 mM GSH; (ii) 80 mL of the dialysis buffer containing 0.5 M Gdn-HCl, 0.4 M L-arginine, 1 mM GSSG, and 2 mM GSH; and (iii) 300 mL of PBS (10 mM sodium phosphate buffer, pH 7.4, containing 0.15 M NaCl). Protein concentrations were determined with a Bio-Rad protein assay reagent using human IgG (Sigma-Aldrich) as standard protein.

2.5. SDS-PAGE and Western blotting

The purified scFv proteins were analyzed with SDS-PAGE (5-20 % gradient polyacrylamide gel) under reducing or non-reducing conditions. Separated proteins were stained with Coomassie Brilliant Blue (CBB). For immunoblotting, the proteins on the SDS-PAGE gel were transferred onto a polyvinylidene difluoride (PVDF) membrane (Millipore, Billerica, MA, USA). The membrane was blocked with PBS containing 3% BSA for 2 h at room temperature. The membrane was washed with PBS and then incubated with HRP-conjugated anti-His-Tag antibody at room temperature for 1 h. The membrane was washed five times with PBS containing 0.2% Tween 20. Bound primary antibodies were detected with HRP-conjugated secondary antibodies and color development using Ez West blue (ATTO Co., Tokyo, Japan). Alternatively, blotted scFv proteins were detected with His Probe-HRP.

2.6. CD spectra of the purified scFv proteins

CD measurements were performed with a J-820 CD spectrophotometer (JASCO Corporation, Japan). Far-UV CD spectra were recorded at 25°C using 400 µL of each sample in a cuvette with a path length of 2 mm. Spectra were obtained after 10 scans and subtracted from the spectra of the buffer obtained under the same conditions. CD spectra were obtained for 1E6 and 1E8 scFv proteins in PBS buffer, pH 7.4.

2.7. ELISA of the purified and refolded scFv proteins from E. coli cells binding to neoglycolipids or human IgA (hIgA)

Wells of a 96-well plate were coated with T-antigen-, Tn-antigen-, and Man3-E6-BDB pre-mixed with E6-

*Underlined italic sequences are restriction sites for enzymes.*
BDB at a ratio of 50 pmol:450 pmol per well. E6-BDB was used as a control. 1E6 and 1E8 scFv proteins were diluted with 20 mM Tris-HCl containing 1% BSA and 0.005% Tween 20 to a concentration of 1.67 μM and incubated at 37°C for 1 h. Unbound scFvs were washed three times with 200 μL of 10 mM Tris-buffered saline, pH7.4 (TBS). Anti-His-tag mouse monoclonal antibody was used as a primary antibody for detection of scFv proteins. After HRP-conjugated second antibody treatment, 100 μL of ABTS solution was added for color development. The reaction was stopped by 100 μL of 1% oxalic acid. Absorbance at 415 nm was measured with a plate reader (Bio-Rad, Hercules, CA, USA).

Alternatively, human immunoglobulin A (hiIgA) was used as a natural glycoprotein ligand since IgA contains six varieties of O-glycans, including T-antigen, in the hinge region (22). Wells of a 96-well plate were coated with human IgA class 1 (50 μg/mL) and then blocked with 3% BSA/TBS. ScFv proteins at concentrations of 85 nM and 420 nM were added to the hiIgA-immobilized wells and incubated at 37˚C for 1h. HRP-conjugated RCA120 lectin (1 μg/mL), which recognizes galactose residues at the non-reducing termini, was used as a positive control. Detection of bound scFvs or RCA was carried out as described above.

2.8. SPR analyses of purified scFv proteins against T-antigen

Real-time measurements of the binding of 1E8 and 1E6 scFv proteins to T-antigen were performed with SPR at 25°C on a Biacore 3000 biosensor (GE Healthcare, Uppsala, Sweden) using 10 mM HEPES, pH 7.4, containing 150 mM NaCl and 0.005% Tween 20 (running buffer) at a flow rate of 20 μL/min. T-antigen pre-immobilized on the sensor chip (D301: Galβ1-3GalNAcα1-6Glc) was purchased from SuDx-Biotec Corp. (Kagoshima, Japan). Since this sensor chip does not contain a dextran matrix, non-specific binding is minimized in comparison to sensor chips such as the CM5 or CM3 that are normally used. 1E6 and 1E8 scFv proteins were injected to T-antigen for 2 min, and then dissociation phases were observed. Alternatively, 1E6 scFv protein was measured using T-antigen biotin-immobilized on the sensor chip SA with glucose-biotin as a negative control. To reduce non-specific binding to the sensor chip surface, NaCl was added to the analyte solutions to reach a final concentration of 0.3 M NaCl. Samples were injected to ligands for 4 min, and then dissociation phases were observed.

During SPR experiments, flow cells were regenerated by injection of the running buffer containing 3.5 M Gdn-HCl followed by thorough washing with the running buffer. Kinetics parameters were calculated using BIAevaluation software version 3.2. These sensorgrams were fitted to a 1:1 Langmuir binding model using a simultaneous non-linear program.

3. Results

3.1. Expression, purification, and refolding of anti T-antigen 1E8, 1E6, 1E10, and 1G11 scFv proteins from E. coli cells

Anti T-antigen 1E8, 1E6, 1E10, and 1G11 scFv proteins were purified from inclusion bodies, prepared from 40 mL of the culture medium, by solubilization with 3.5 M Gdn-HCl. These scFv proteins were subjected to Ni²⁺-Sepharose chromatography in the presence of 3.5 M Gdn-HCl and they were then refolded by stepwise dialysis (19,23). Figures 1A and B show comparable results of SDS-PAGE followed by Coomassie Brilliant Blue (CBB) staining and Western blot analyses for the four scFv proteins purified and refolded from the respective inclusion bodies. Figure 1 shows the starting material for the purification of the scFv proteins in the inclusion bodies (lane 1) as well as the scFv proteins

Figure 1. SDS-PAGE (A) and Western blot (B) analyses of 1E8, 1E6, 1E10, and 1G11 scFv proteins prepared from inclusion bodies by purification and refolding. Shown are results for inclusion bodies (lane 1) and soluble (lane 2) and insoluble (lane 3) fractions after purification and refolding. Proteins were visualized by CBB-staining (A). Western blot analyses were carried out using an HRP-conjugated anti-His-tag mouse monoclonal antibody (B).
recovered from the soluble and insoluble fractions after refolding (lanes 2 and 3, respectively). A summary of purification and refolding of all four scFv proteins is presented in Table 2. 1E8, 1E6, and 1E10 scFv proteins were effectively recovered from the soluble fractions (Figure 1A, lane 2), indicating that most of the scFv proteins are folded. In contrast, 1G11 scFv protein was not readily recovered from the soluble fraction. While 1E8 expression was the lowest among the four scFv proteins, its efficient recovery from the soluble fraction allowed its further characterization. Each refolded scFv protein contained basically a single protein band (Figure 1), confirming it’s near homogeneity. The molecular size of the 1E10 scFv protein was smaller than its theoretical molecular weight (Figure 1). 1E10 scFv protein moved faster than 1G11 scFv protein, which is an incomplete scFv lacking CDRs in its VL domain (11).

3.2. Structural characterization of purified 1E6 and 1E8 scFv proteins

CD spectroscopy was used to determine the secondary structures of the refolded scFv proteins (Figures 2A and 2B). Proteins with β-sheet structures are known to show a single negative peak with a minimum at 217 nm (24). The purified 1E6 and 1E8 scFv proteins showed a single negative peak with a minimum at approximately 217 nm. In the CD spectra, the molar ellipticity at 217 nm was −6,500 for the 1E6 scFv proteins and −2,500 for the 1E8 scFv proteins.

3.3. Binding of the 1E6 and 1E8 scFv proteins to T-antigen according to ELISA and SPR

ELISA was performed using two types of T-antigen ligands: synthetic and natural. First, the binding of scFv proteins to neoglycolipids was analyzed (Figure 3A). Both 1E6 and 1E8 scFv proteins bound to T-antigen E6-BDB but not to GalNCA-E6-BDB (Tn-antigen-E6-BDB) or mannotrioise-E6 BDB (Man3-E6-BDB). Second, human IgA (hIgA)-containing galactose at the non-reducing termini was used to determine the T-antigen activity of the 1E8 and 1E6 scFv proteins (Figure 3B). A galactose-specific lectin, RCA\textsubscript{120}, was used as the positive control. Results clearly demonstrated that the 1E6 scFv protein had binding activity to hIgA whereas 1E8 scFv protein did not bind to hIgA.

SPR analyses were performed to further confirm the T-antigen binding activity of both the 1E6 and 1E8 scFv proteins (Figure 4). Kinetic parameters of 1E8 scFv and 1E6 scFv binding to T-antigen are summarized in Table 3. Both the 1E8 and 1E6 scFv proteins had good affinity for D301 (T-antigen-immobilized sensor chip) (Figures 4A and 4B, respectively), as indicated by respective $K_D$ values of $8.3 \times 10^{-8}$ M and $1.3 \times 10^{-6}$ M (Table 3). 1E6 scFv protein was analyzed using the biotinylated T-antigen sensor chip (Figure 4C) and was found to have $K_D = 8.0 \times 10^{-7}$ M (Table 3).

### 4. Discussion

The current authors and their colleagues previously isolated genes encoding human scFv proteins with specificity against various carbohydrate moieties from a phage library displaying human scFv proteins (8-12). Eleven anti-T-antigen phage clones were isolated from a phage library and categorized into four groups (11). An anti-T-antigen 1G11 scFv protein from Group 4 was purified by DEAE-cellulose and Ni$^{2+}$-Sepharose affinity chromatography from the solubilized fraction of *E. coli* cells transfected with a phagemid bearing the 1G11 scFv gene (11). More recently, a Group 1 1E8 scFv protein was successfully expressed and purified in a *Drosophila* S2 expression system (21).

The current study used an *E.coli* expression system to purify and characterize four anti-T-antigen scFv proteins from Groups 1-4 (11). Two anti-T-antigen scFv proteins, 1E8 and 1E6 respectively belonging to Groups 1 and 2, were successfully purified for further characterization. *E. coli* strains, such as BL21(DE3), produce native bacterial proteins that exhibit a high affinity for divalent cations like nickel. Such native bacterial proteins may be co-purified with His-tagged recombinant proteins via Ni$^{2+}$-Sepharose chromatography (25). The use of inclusion bodies consisting of mostly recombinant proteins as the starting material could help avoid this problem of contamination. Inclusion bodies were denatured under mild conditions in 3.5 M Gdn-HCl and His-tagged scFv proteins were purified using Ni$^{2+}$-Sepharose column chromatography in the presence of 3.5 M Gdn-HCl. The purified scFv proteins were refolded by step-wise dialysis in the presence of arginine according to previously reported procedures (23). As shown in Table 2, 1E6 scFv protein was purified with the highest yield.

</table>
among the four scFv proteins. The level of production, 30 mg from a 1 L culture, was within the range expected from this procedure. Interestingly, when an alternative Drosophila S2 cells expression system was used to produce anti-T-antigen scFv proteins, we found that in contrast to this study, properly-folded 1E8 scFv protein was more efficiently expressed than 1E6 scFv protein (21).

The secondary structure formed by the refolded 1E8 and 1E6 scFv proteins was assessed using CD spectrometry. The far-UV CD spectra of the refolded scFv proteins revealed that both scFvs possess a β-sheet structure that is characteristic of such immunoglobulin fragments (24,26). The CD spectrum of 1E6 scFv indicates that it has a β-sheet structure with most of its proteins folded correctly. The CD spectrum of 1E8 scFv indicates the presence of a β-strand structure that is not as deep. This CD spectrum indicates that both correctly folded and unfolded proteins may be present in the refolded 1E8 scFv sample, suggesting that improvements on refolding procedures are required for purification of 1E8 scFv protein from inclusion bodies. The 1E8 scFv protein expressed in Drosophila S2 cells, however, was found to be qualitatively much better than E. coli-expressed and properly refolded as judged by CD and NMR (21).

1E10 scFv protein should have a molecular mass similar to those of 1E6 and 1E8, but the 1E10 scFv protein moved faster than both 1E6 and 1E8 scFv proteins according to SDS-PAGE (Figure 1). This indicates that the expressed 1E10 scFv protein may not be intact. There is no apparent explanation for the production of 1E10 scFv protein with a smaller molecular mass, so further study is needed.

Both 1E8 and 1E6 scFv proteins specifically bound to T-antigen-E6-BDB, which was the T-antigen probe used to screen phages displaying scFv proteins (Figure 3A). When phage antibodies representing 1E8, 1E6, 1E10, or 1G11 scFv proteins were originally analyzed for specificity, 1E8, 1E6, and 1E10 bound to T- and Tn-antigen equally whereas 1G11 bound specifically to T-antigen (II). The results of the current study confirm that both 1E8 and 1E6 scFv proteins exhibit T-antigen specificity. 1E6 scFv bound to hlgA, but binding of 1E8 scFv to hlgA was not detected (Figure 3B). The reason for the poor binding of 1E8 scFv protein to hlgA is not apparent. The binding activity of 1E8 scFv protein with T-antigen has been confirmed since it bound to T-antigen moieties conjugated to lipid (Figure 3A) and gold surfaces (Figure 4A).

Table 3 summarizes the kinetic parameters calculated from the sensorgrams shown in Figure 4. The results indicate that the 1E6 scFv protein bound similarly to T-antigen that was immobilized covalently on the gold surface (D301), or via biotin to SA, with a KD of approximately $1 \times 10^{-6}$ M. 1E8 scFv bound to D301 with an affinity of approximately $1 \times 10^{-7}$ M. These results demonstrate that both 1E6 and 1E8 scFv proteins have a definite affinity for T-antigen, with the former having a lower affinity (one order) than the latter. Since protein-carbohydrate interactions are generally weak, these human scFv proteins with rather high affinities for oncofetal T-antigen have high potential for future development of cancer therapeutics. For example, an anti-T-antigen monoclonal antibody JAA-F11 has been shown to block the adhesion of human and mouse tumor cells in metastatic models in in vitro and in vivo studies (27). Further characterization of 1E8 and 1E6 scFv proteins, their affinity improvement, and their effects on tumor growth and metastasis will be needed for future clinical application of these scFv proteins.

In conclusion, this study successfully purified and compared four anti-T-antigen scFv proteins from inclusion bodies expressed in E. coli cells. Although four anti-T-antigen scFv genes belonging to Groups 1-4 were expressed and produced in an E. coli expression system, 1E6 and 1E8 scFv proteins were produced at sufficient levels for further characterization of their T-antigen binding. Specificity and affinity constants determined using ELISA and SPR, respectively, provided evidence that Group 1 and 2 scFv proteins are T-antigen-specific and suggested that 1E8 scFv protein has a higher affinity for T-antigen than 1E6 scFv protein.

Acknowledgements

The authors wish to thank Dr. Ayano Matsumoto-Takasaki for her significant contribution to the first part of this project. The authors also wish to thank Dr. Hitoo Iwase, Kitasato University Medical School, and Drs. Hiroko Kawakami and Kazunori Toma, the Noguchi Institute, for providing IgA and neoglycolipids, respectively. Finally, the authors wish to thank Drs. Hiroshi Kamiguchi and Tadayuki Sato, Education and Research Support Center of Tokai University, for their valuable technical assistance. This work was supported by a grant 22570125 from the Japan Society of the Promotion of Science (JSPS).

Summary

The present study is designed to search for the serum cytokine biomarker for liver injury induced by *Dioscorea bulbifera* L., which is a traditionally used herbal medicine in China. Mice were orally given various doses of ethyl acetate extract (EF) isolated from *D. bulbifera* for 12 days. The activity of serum alanine/aspartate transaminases (ALT/AST) was increased in EF (400 mg/kg)-treated mice. Histological assessment further confirmed EF (400 mg/kg)-induced liver injury. Results of a cytokine-antibody array demonstrated that there were 10 cytokines up-regulated and 1 cytokine down-regulated in EF (400 mg/kg)-treated mice. Enzyme-linked immunosorbent assay (ELISA) further confirmed the increased level of CD30 ligand (CD30L) and decreased level of interleukin-3 (IL-3) in EF-treated mice. In conclusion, our results demonstrate that the altered expression of CD30L and IL-3 may be potential biomarkers for hepatotoxicity induced by *D. bulbifera*.

Keywords: *Dioscorea bulbifera* L., hepatotoxicity, cytokines, CD30L, IL-3

1. Introduction

*Dioscorea bulbifera* L. is a native plant in Africa and Asia, and it is also an invasive species in many tropical areas, including Florida in the United States. *D. bulbifera* is generally used to treat thyroid disease (especially goiter) and cancer in clinics in China (1). However, during clinical practice *D. bulbifera* has been found to have hepatotoxicity, which has caused a great obstacle for its application in the clinic (2). Recently, study of the hepatotoxicity of *D. bulbifera* has attracted great interest. Our previous studies have already showed that an ethyl acetate extract (EF) isolated from *D. bulbifera* could induce oxidative stress liver injury (3,4). Meanwhile, our studies and other reports found that diterpenoids were the main hepatotoxic compounds in *D. bulbifera*, such as diosbulbin B and diosbulbin D (3,5).

Drug-induced liver injury (DILI) has been a public health issue for many years, and it is the major cause for withdrawal of approved drugs from the market and leads to blockage of development of potential drugs. Generally, herbal medicines are regarded as having no toxicity or side-effects, and they are increasingly used worldwide as dietary supplements (6,7). However, there are increased reports about the hepatotoxicity induced by herbal medicines. For example, herbal medicines as dietary supplements caused about 9% of cases of DILI, while in Asia the percentage was about 20-55% cases of DILI (8,9). Thus, liver injury induced by herbal medicines needs to be paid more attention.

Currently, conventional widely used biochemical markers for evaluating liver injury are serum alanine aminotransferase (ALT), aspartate aminotransferase (AST), and cholestatic markers such as alkaline phosphatase (ALP), and γ-glutamyltransferase (γGT) (10,11). However, all of these biomarkers sometimes can not accurately reflect liver injury (11). Serum ALT activity has also been associated with toxicity of other organs and thus it leads to false positives due to other sources of serum ALT activity because it has specificity beyond the liver (12). Meanwhile, there is a report that serum ALT activity is variable in people, which will also lead to possible false positive or negative results.
Thus, searching for more simple and sensitive biomarkers as a supplementary index for DILI is an urgent problem that needs to be solved.

Cytokines are a diverse group of soluble proteins, peptides or glycoproteins, which have various biological functions. Recently, innate and acquired immunity mediated by cytokines has been reported to play a critical role in DILI, and thus cytokines have the potential value as biomarkers for DILI (14,15). In the present study, we employed a cytokine-antibody array to search for potential cytokine biomarkers for liver injury induced by *D. bulbifera*.

2. Materials and Methods

2.1. Chemicals and reagents

The rhizomes of *D. bulbifera* were collected in Qingyang, Anhui Province and authenticated by Prof. Shou-Jin Liu (Anhui College of Traditional Chinese Medicine, Anhui, China). The specimens were deposited in the herbarium of the Institute of Chinese Materia Medica, Shanghai University of Traditional Chinese Medicine. The preparation of ethyl acetate extracts (EF) isolated from *D. bulbifera* was previously reported in our published papers, and the content of diosbulbin B is 13.72% (16). The kits for determining ALT/AST activity were obtained from Jiancheng Bioengineering Institute (Nanjing, Jiangsu, China). RayBio™ Mouse Cytokine Antibody Array III was purchased from RayBiotech, Inc. (Norcross, GA, USA). ELISA kits were purchased from RapidBio (West Hills, CA, USA). Other reagents unless indicated were purchased from Sigma Chemical Co. (St. Louis, MO, USA).

2.2. Experimental animals

Specific pathogen free male ICR mice (18-22 g body weight) were purchased from the Chinese Academy of Sciences (Shanghai, China). The mice were fed a standard laboratory diet and given free access to tap water, kept in a controlled room temperature (22 ± 1°C), humidity (65 ± 5%), and a 12:12-h light/dark cycle. All mice received humane care in compliance with the institutional animal care guidelines approved by the Experimental Animal Ethical Committee of Shanghai University of Traditional Chinese Medicine.

2.3. Treatments of animals

Mice were orally administered EF (100, 200, and 400 mg/kg, suspended in 0.5% CMC-Na, n = 7) for 12 days, and 0.5% CMC-Na was used as a vehicle control (n = 8). Animals were killed 24 h after the last administration. Blood was collected from the eyeball for measurement of ALT, AST, and cytokine analysis. Livers were collected for histological assessment.

2.4. Serum ALT/AST analysis

Blood samples obtained from mice of all groups were allowed to coagulate for 2 h on ice. Serum was then isolated following centrifugation at 840 × g for 15 min. Serum ALT, and AST activity were measured with kits according to the manufacturer's instructions.

2.5. Histological examination

Portions of the liver were fixed in 10% formalin and embedded in paraffin. Samples were subsequently sectioned (5 µm) and stained with hematoxylin-eosin (HE) for further histological analysis.

2.6. Cytokine antibody array

Serum cytokines were assayed by Raybio Mouse Cytokine Antibody Array III according to the manufacturer’s instructions. This array is capable of simultaneously detecting 62 different cytokines with high specificity. Chemiluminescence signals were visualized by exposure to light sensitive films. Films were digitized, and densitometric quantifications were analyzed with ScanAlyze software, and then the ratio of EF/Control was calculated. Differentially expressed cytokines were defined as over 2 fold alteration between the control and EF-treated groups.

2.7. ELISA analysis

Serum was used for ELISA analysis according to the manufacturer's instructions.

2.8. Statistical analysis

The results were expressed as Means ± SEM. SPSS 18.0 was used for statistical analysis. Significance difference between various groups was determined by One-Way ANOVA, and between two groups was evaluated by an independent-sample *t*-test. *p* < 0.05 was considered as indicating statistically significant differences.

3. Results

3.1. EF induced liver injury

As shown in Figure 1A, EF (400 mg/kg) increased serum ALT and AST activity (*p* < 0.001). Further, histological assessment showed normal liver shape and structure in control mice (Figure 1B). EF (400mg/kg)-treated mice exhibited severe liver damage indicated by intrahepatic hemorrhage, lymphocyte infiltration and the destruction of liver structure (Figure 1B).

3.2. Distinct serum cytokine expression in normal and EF-treated mice
To identify the cytokine biomarker for *D. bulbifera*-induced liver injury, we analyzed the content of 62 cytokines in serum by a cytokine antibody array in control and EF (400 mg/kg)-treated mice. Table 1 is the layout of the cytokine antibody array, and Figure 2 is the results of the array. After analyzing, as shown in Table 2, ten cytokines were up-regulated and one cytokine was down-regulated over 2-fold in EF (400 mg/kg)-treated mice as compared to control. The up-regulated cytokines are CD30L, fractalkine, interferon inducible monokine (CRG2), granulocyte macrophage colony-stimulating factor (GM-CSF), thymus-expressed chemokine (TECK), monocyte chemoattractant protein 5, IL-4, IL-9, IL-12 p70, and TNF-α.

5, IL-6, and axl receptor tyrosine kinase (Axl), while the down-regulated cytokine is IL-3.

3.3. ELISA assay of changed cytokine

Next, ELISA assays were used to validate the change of those cytokines in the cytokine antibody array. Figure 3A showed that CD30L was increased and IL-3 was decreased in EF (400 mg/kg)-treated mice ($p < 0.05$), which is consistent with the results of the cytokine antibody array. There were no obvious changes of other cytokines such as fractalkine, CRG2, GM-CSF, TECK, MCP-5, IL-5, IL-6, or IL-4 (Figures 3A and 3B), which is inconsistent with the results of the cytokine antibody array. Growth arrest-specific 6 (Gas 6), the ligand for axl receptor tyrosine kinase (Axl), was decreased in EF (400 mg/kg)-treated mice ($p < 0.05$) in the ELISA assay (Figure 3C).

4. Discussion

In China, *D. bulbifera* is traditionally used to treat thyroid disease. Recently, *D. bulbifera* has been found to have a good therapeutic effect for some solid cancers, and now is commonly used in cancer therapy in the clinic. However, with the increased application of *D. bulbifera* in the clinic, its induced hepatotoxicity has widely attracted attention. The present study shows that after treatment with EF isolated from *D. bulbifera* for 12 days, serum ALT and AST activities were increased. Further, histological assessment demonstrated liver destruction in EF-treated mice. All of these results indicate the potential hepatotoxicity of *D. bulbifera*, when used for a stage treatment in cancer therapy.

Inflammation is reported to contribute to progressive liver damage induced by exogenous chemical hepatotoxins including drugs like acetaminophen, cycloheximide etc. (17-20). Cytokines are a family of secreted proteins that promote inflammation and participate in both innate and adaptive immune responses which play important roles in DILI (15,21,22). To our knowledge the present study is the first study using a cytokine antibody array to identify potential serum biomarkers for DILI. In the study, the primary screen using cytokine antibody array demonstrated 11 cytokines differentially altered after treatment with EF. Further, ELISA results confirmed that 2 cytokines were significantly changed after treatment with EF, which are CD30L and IL-3. The other 9 cytokines were not changed when measured by ELISA, which may be due to the limitations of the cytokine antibody array. There is already a report demonstrating that a linear response between the chemiluminescent signal and quantity may not always exist, which may lead to the false results shown in the cytokine antibody array (23), so further verification experiments such as ELISA are necessary.
CD30L is the ligand for CD30, which represents the newest member of the tumor necrosis factor receptor (TNF-R) family (24). Up-regulation of CD30/CD30L is associated with several hematological malignancies such as Hodgkin’s disease (HD), anaplastic large cell lymphoma (ALCL) and subsets of Non-Hodgkin’s lymphomas (NHL’s) (25). Recently, the interaction of CD30/CD30L was reported to play some role in the crosstalk between natural killer and dendritic cells, and is critical for humoral immunity (26,27). Meanwhile, some studies demonstrate that CD30/CD30L might be useful as a novel biological therapy for allergic rhinitis, inflammatory bowel disease, autoimmune diabetes, and chronic inflammatory skin diseases like psoriasis or atopic dermatitis (28-31). However, there is no report about whether there is some role of CD30L in liver injury. The present study found that serum CD30L was increased in EF-treated mice, which suggests potential involvement of CD30L in D. bulbifera-induced liver injury. This result is the first report about the potential role of CD30L in liver injury, and the concrete mechanism needs further investigation.

IL-3 is a key cytokine which promotes survival, proliferation, differentiation and maturity of bone marrow-derived hematopoietic stem cells, and thus it is widely studied to treat different states of bone marrow failure or hematologic malignancies (32,33). In addition, recent studies demonstrate that IL-3 participates in the response of the organism to various types of stress (34). Although there are already reports about the change of IL-3 in hemorrhage or alcohol-induced liver injury, the role of IL-3 in liver injury is still not clear (35,36). Our results demonstrate the down-regulation of serum IL-3 in EF-treated mice, which suggest potential involvement of IL-3 in D. bulbifera-induced liver injury.

In conclusion, the present study demonstrates that serum CD30L and IL-3 levels were up-regulated and down-regulated respectively in EF-treated mice, which demonstrates that inflammation may contribute to the liver injury induced by D. bulbifera, and the concrete mechanism needs further investigation.

Summary

The skin of \textit{Bufo bufo gargarizans} Cantor has long been used for the treatment of hepatitis B in China and supercritical carbon dioxide extraction (SC-CO\textsubscript{2}) is widely used in extracting active ingredients from natural products. The aim of present study was to assess the anti-hepatitis B virus (HBV) effect of the supercritical CO\textsubscript{2} extract from the skin of \textit{Bufo bufo gargarizans} Cantor (SCE-BC). Cytotoxicity of SCE-BC was analyzed using an MTT \textsuperscript{[3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide]} assay in HepG2.2.15 cells. The hepatitis B surface antigen (HBsAg), hepatitis B e antigen (HBeAg), and hepatitis B core-related antigen (HBcrAg) concentrations in cell culture medium were determined by chemiluminescent enzyme immunoassay. HBV mRNA in cells was determined using real-time polymerase chain reaction. SCE-BC concentrations below 10\textsuperscript{-2} μg/mL had no significant toxicity to HepG2.2.15 cells. SCE-BC at 10\textsuperscript{-4} μg/mL effectively inhibited the secretion of HBeAg by 23.36% on day 6. It was more potent than the positive control lamivudine (100 μg/mL) in terms of the inhibition of HBeAg and HBcrAg secretion on day 6. Consistent with the HBV antigen reduction, HBV mRNA expression was markedly inhibited in comparison to the control when HepG2.2.15 cells were treated with SCE-BC. Moreover, SCE-BC had greater inhibitory activity with respect to HBeAg than to HBsAg. Since HBeAg promotes immune tolerance and persistent infection during HBV infection, the present results suggest that immune tolerance induced by HBeAg might be overcome by SCE-BC. Therefore, SCE-BC warrants further investigation.

Keywords: Hepatitis B virus, traditional Chinese medicine, \textit{Bufo bufo gargarizans} Cantor, HepG2.2.15 cells

1. Introduction

Hepatitis B virus (HBV), a member of the hepadnavirus (hepatotropic DNA viruses) family, infects approximate 400 million people, making it the most common chronic infectious disease worldwide (1). Chronic HBV infection can lead to cirrhosis, liver failure, and hepatocellular carcinoma, accounting for more than a million global deaths annually (2,3). Currently, only several antiviral drugs, including interferon-α and lamivudine (3TC), have been approved for the treatment of hepatitis B. However, the therapeutic effect of interferon-α and 3TC may be accompanied by adverse effects and drug resistance following prolonged administration (4,5). Therefore, there remains an urgent need for alternative drugs against HBV. Traditional Chinese medicines (TCMs), widely used to treat
hepatitis B in China and many parts of the world (6), could provide a great opportunity for screening safe and more effective anti-HBV agents.

The venom and skin of toad Bufo bufo gargarizans Cantor has long been used in TCM (7,8). Chansu, a preparation of toad venom, has been used for the treatment of canker sores, toothache, sinusitis, and local inflammations in China for many years (7). Cinobufacini (Huanchansu), the aqueous extract of the Bufo bufo gargarizans Cantor skin, is a Chinese medicine and has been extensively used in clinics to treat a number of diseases, such as malignant tumors, chronic hepatitis B, and systemic and local infection (9–12). It is reported the negative conversion rates of HBsAg and HBeAg increased significantly in patients treated with cinobufacini compared to the control group (patients untreated with cinobufacini) (13). Moreover, abnormal serum hepatic enzyme levels significantly decreased after treatment. In our previous study, cinobufacini at 1 μg/mL effectively inhibited the secretion of HBsAg and HBeAg by 29.58 and 32.87% in HepG2.2.15 cells on day 6. It was more potent than lamivudine (100 μg/mL), which served as a positive control (14).

In recent years, some new techniques, including ultrasonic extraction and supercritical carbon dioxide extraction (SC-CO₂), are widely used in extracting active ingredients from traditional Chinese medicine. SC-CO₂, is a separation technique based on the enhanced solvating power of CO₂ above its critical point (15). This technology has advantage over traditional technology because of the non-toxic, non-flammable characteristics of CO₂ and its availability in high purity with low cost. Moreover, CO₂ has low critical temperature (31.1°C) and low critical pressure (73.8 bar). Therefore CO₂ can be treated as an ideal solvent for extraction of natural products (16). Our previous study indicates the aqueous extract of the Bufo bufo gargarizans Cantor skin cinobufacini possess significant activity against HBV (15). However, it is still unclear whether the supercritical CO₂ extract from the skin of Bufo bufo gargarizans Cantor (SCE-BC) possess the activity against HBV. In the present study, in order to search and develop more effective anti-HBV drug, SCE-BC was investigated for the inhibition of HBV replication and secretion of HBV antigen in HBV-infected hepatocytes.

2. Materials and Methods

2.1. Drugs

SCE-BC, which was prepared by extracting 10 g of the toad skin with dynamic extraction using 200 mL of CO₂ at 40°C and 20 MPa followed by concentration to 1 mL, was obtained from Anhui China Resources Jinchan Pharmaceutical Co., Ltd. (Anhui, China). It was dissolved in dimethylsulfoxide (DMSO) as a 100 mg/mL stock solution and kept at 4°C. 3TC was from Moravek Biochemicals (Brea, CA, USA) and served as the positive control. Dilutions of the drugs were performed on the day of medium change. The final concentration of DMSO in the samples was less than 0.001% (v/v).

2.2. Cell culture and treatment

The human HBV-transfected cell line HepG2.2.15 (17) was maintained in RPMI 1640 medium supplemented with 10% fetal calf serum (both from Gibco-Invitrogen, Carlsbad, CA, USA), 100 units/mL penicillin, 100 μg/mL streptomycin, and 200 μg/mL G418 (all from Sigma, St Louis, MO, USA) at 37°C in a humidified incubator with 5% CO₂. Cells were maintained for 24 h before treatment to reach confluence. The confluent HepG2.2.15 cells were treated with SCE-BC or 3TC at various concentrations in serum-free medium for 3 days or 6 days. The culture medium was replaced with a fresh one on day 3, with or without (negative control conditions) different concentrations of SCE-BC or 3TC during the 6-day experiment.

2.3. Cytotoxicity assay

HepG2.2.15 cells were seeded in 96-well plates at a density of 1.5 × 10⁴ per well and treated with different concentrations (10⁻¹, 10⁻², 10⁻³, 1, or 10 μg/mL) of SCE-BC for 3 or 6 days. The cytotoxicity of SCE-BC was analyzed with an MTT [3-(4,5-dimethylthiazol-2yl)-2,5-diphenyltetrazolium bromide] assay using the Cell Proliferation Kit I (Roche, Mannheim, Germany) following the manufacturer’s instructions. Each experiment was performed in triplicate. The cell viability was expressed as a percentage of the control.

2.4. Measurement of HBV antigens

HepG2.2.15 cells were seeded in 6-well plates at a density of 4.5 × 10⁵ per well for measurement of HBV antigens. After incubation with various concentrations of SCE-BC or 3TC for 3 or 6 days, the culture medium was collected, cell debris was removed, and the result was stored at -70°C until analysis. Hepatitis B surface antigen (HBsAg), hepatitis B e antigen (HBeAg), and hepatitis B core-related antigen (HBcrAg) in culture supernatants of HepG2.2.15 cells were respectively measured with a Lumipulse® II or I kit or HBcrAg kit (Fuji Rebio, Tokyo, Japan). These kits use a method of chemiluminescent enzyme immunoassay (CLEIA) based on the chemiluminescent capture of specific antigen–antibody reactions.

2.5. Quantification of HBV DNA in the culture medium

The HBV viral load in culture supernatants of HepG2.2.15 cells was quantified with a HBV DNA
quantitative kit (SRL, Tokyo, Japan). This kit is based on transcription-mediated amplification and hybridization protection assay (18). Briefly, a mixture of 10 μL of cell culture supernatants or amplification standards, Sample Diluent I, Sample Diluent II, and Primer Reagent and 50 μL of oil were placed in a reaction tube. The tube was heated at 95°C for 10 min and then incubated at 37°C for 5 min. Neutralization reagent and reconstituted amplification reagent solution were added and the reaction mixture was incubated at 37°C for 3 h. RNA amplicons were detected with a hybridization protection assay. The measurement range was 3.7-8.7 log genome equivalent/mL (LGE/mL).

2.6. Determination of HBV RNA

Total RNA was isolated from HepG2.2.15 cells using Trizol reagent (Invitrogen) in accordance with the manufacturer’s instructions. The mRNA was then reverse-transcribed to make cDNA using a QuantiTect Rev. Transcription Kit (Qiagen GmbH, Hilden, Germany) and oligo dT primer following the manufacturer’s instructions. The cDNA was quantified using the Thermal Cycler Dice™ Real Time System (Takara, Shiga, Japan). The polymerase chain reaction (PCR) was performed using primers (synthesized by Invitrogen): HBV surface region F 5’-GCCAAAATTCGCAGTCC-3’ and R 5’-ACGGGCAACATACCTT-3’; HBV core region F 5’-AGACCCACAAATGCCCCCTAT-3’ and R 5’-GATCTTTCTCAGCAGCGGA-3’; glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (internal control) F (h) 5’-AGGGGTCATTgATGGCAACAATATCCA-3’ and R (h) 5’-TTTACCAGAGTTAAAGCAGCCCTGGTG-3’. Controls included water blanks and RNA extracts that were not subjected to reverse transcription. A series of dilutions of Topo-HBV plasmid containing HBV genes and Topo-GAPDH plasmid containing GAPDH cDNA were used to create standard curves for quantifying HBV and GAPDH mRNA levels, respectively. These plasmid concentrations were as follows (copy/μl): 10², 10³, 10⁴, 10⁵, 10⁶, 10⁷, and 10⁸. Taq readymix with SYBR green (Sigma, St Louis, MO, USA) was used to amplify and detect DNA during the reaction. Thermal cycling parameters for the HBV core region and GAPDH consisted of a hot start for 2 min at 94°C followed by 40 cycles of 9 °C for 15 s, 60°C for 30 s, and then 72°C for 40 s. Thermal cycling parameters for the HBV surface region consisted of a hot start for 2 min at 94°C followed by 45 cycles of 94°C for 15 s, 58°C for 30 s, and then 72°C for 30 s. Specificity of the polymerase chain reaction products was verified by melting curve analysis and agarose gel electrophoresis.

2.7. Measurement of active components resibufogenin and cinobufagin using HPLC

To compare active components resibufogenin and cinobufagin in cinobufacini and SCE-BC, we performed HPLC. HPLC conditions: reversed-phase COSMOSIL Cholester C-18 column (Waters, 4.6 mm × 150 mm, 5 μm); mobile phase, 45% acetonitrile; flow rate, 1 mL/min; detection wavelength, 200-400 nm.

2.8. Statistical analysis

All the items determined in this study were repeated at least three times, and the results were expressed as mean ± S.D. Statistical significance was determined using analysis of variance (ANOVA) or a rank sum test and an independent-samples t test. A value of \( p < 0.05 \) was considered statistically significant.

3. Results

3.1. Cytotoxic effect of SCE-BC on HepG2.2.15 cell viability

The viabilities of the HepG2.2.15 cells in the presence of different concentrations of SCE-BC were examined with a MTT assay. The results showed that SCE-BC concentrations below \( 10^{-2} \) μg/mL had no significant toxicity to HepG2.2.15 cells (Figure 1). SCE-BC significantly inhibited the growth of HepG2.2.15 cells at concentrations above \( 10^{-2} \) μg/mL. The cytotoxicity of SCE-BC was examined to determine the treatment concentrations in the following HepG2.2.15 cell culture experiments.

3.2. Effects of SCE-BC on HBV antigens and DNA

In this anti-HBV assay, HepG2.2.15 cells were treated with different concentrations of SCE-BC for 3 or 6 days. On day 3, SCE-BC at concentrations of \( 10^{-4} \) μg/mL decreased HBsAg secretion by 8.08%.
and the positive control 3TC (100 μg/mL) decreased HBsAg secretion by 21.88%. SCE-BC at concentrations of $10^{-3}$ and $10^{-2} \mu g/mL$ inhibited HBeAg secretion on day 3 and 6 (Table 2). Moreover, on day 6 SCE-BC at a concentration of $10^{-4}$ exhibited more potent activity than the positive control 3TC (100 μg/mL) in terms of the inhibition of HBeAg secretion. SCE-BC at a concentration of $10^{-4}$ decreased HBeAg secretion by 23.36% while 3TC at 100 μg/mL reduced the secretion of this antigen by 20.81%. Based on this analysis, SCE-BC has greater inhibitory activity with respect to HBeAg than to HBsAg. SCE-BC at concentrations of $10^{-4}$ and $10^{-2} \mu g/mL$ had no action on HBcrAg secretion in the culture medium on day 3 (Table 3). However, on day 6 SCE-BC exhibited more potent activity than the positive control 3TC (100 μg/mL) in terms of the inhibition of HBcrAg secretion. There were no significant differences between SCE-BC treatment and the control in terms of the HBV DNA levels in the culture medium (Table 4).

### 3.3. Effect of SCE-BC on HBV mRNA expression

To determine if the effects of SCE-BC on HBV antigen expression were induced by decreases in HBV RNA

LGE/mL: log genome equivalent/mL.
levels, real-time PCR analysis was performed using total RNA isolated from HepG2.2.15 cells. When treated with SCE-BC at a concentration of $10^{-4}$ μg/mL for 6 days, inhibition of HBV mRNA was observed with a 33.64% reduction in the HBV surface/GAPDH mRNA ratio and 61.06% reduction in the HBV core/GAPDH mRNA ratio in comparison to controls (Figure 2). These results showed that the HBV mRNA expression was markedly inhibited in comparison to the control when HepG2.2.15 cells were treated with SCE-BC at a lower concentration. This finding revealed that the inhibitory effects of SCE-BC on HBV antigens would be induced by the specific inhibition of HBV mRNA expression.

3.4. Content of active components resibufogenin and cinobufagin

The levels of resibufogenin and cinobufagin were measured using HPLC (Figure 3). The concentrations of resibufogenin and cinobufagin in cinobufacini were respectively 3.20 and 1.56 μg/g of the toad skin, while the concentrations of resibufogenin and cinobufagin in SCE-BC were respectively 121.17 and 33.43 μg/g of the toad skin. The levels of these two active components in SCE-BC were obviously higher than those in cinobufacini.

4. Discussion

The skin of toad Bufo bufo gargarizans Cantor (Bufonidae) has long been used in Chinese medicine for the treatment of hepatitis B in China (11,13,19) and its extract has also been considered to have the efficacy in the management of HBV infection (20). Our previous study indicates the aqueous extract of the Bufo bufo gargarizans Cantor skin, cinobufacini possess significant activity against HBV (14). In the present study, the anti-HBV activity of the supercritical CO$_2$ extract from the toad skin was evaluated in the HepG2.2.15 cell line. SCE-BC at a concentration of $10^{-4}$ μg/mL exhibited more potent activity than the positive control 3TC (100 μg/mL) in terms of the inhibition of HBeAg and HBcrAg secretion after treatment of HepG2.2.15 cells for 6 days. This effect of 3TC was consistent with that noted in a previous report (21). Moreover, no cytotoxicity was observed with SCE-BC at $10^{-4}$ μg/mL. These results clearly revealed that SCE-BC had anti-HBV properties and that its inhibitory activity was not induced by cytotoxicity. Although SCE-BC at $10^{-4}$ μg/mL exhibited lower activity than cinobufacini at 1 μg/mL in terms of the inhibition of HBsAg and HBeAg secretion (14), the concentration of SCE-BC was much lower than the concentration of cinobufacini used to treat HepG2.2.15 cells. Moreover, the levels of two active components resibufogenin and cinobufagin in SCE-BC were obviously higher than those in cinobufacini. The supercritical CO$_2$ extract from the toad skin produced 37-fold and 20-fold increase of the levels of resibufogenin and cinobufagin than the aqueous extract. Therefore, SCE-BC may have better anti-HBV effects than cinobufacini.

![Figure 2](image1.jpg)

Figure 2. Effect of SCE-BC at a concentration of $10^{-4}$ μg/mL on the mRNA levels of HBV from the surface and core regions in HepG2.2.15 cells on day 6. Data shown represent the mean values (± S.D.) based on three independent experiments. Symbols represent statistical significance. * $p < 0.05$ vs. control using an independent-samples t test.

![Figure 3](image2.jpg)

Figure 3. HPLC 3D chromatographic graph of cinobufacini and SCE-BC. (A) The concentrations of resibufogenin and cinobufagin in cinobufacini were respectively 3.20 and 1.56 μg/g of the toad skin. (B) The concentrations of resibufogenin and cinobufagin in SCE-BC were respectively 121.17 and 33.43 μg/g of the toad skin.
The effects of SCE-BC at a lower concentration (10^3 μg/mL) were more potent than those of this drug at a higher concentration (10^2 μg/mL) in terms of inhibiting HBV antigen secretion on day 6. This result could be explained by 18.30% of toxic effect induced by SCE-BC at 10^2 μg/mL on day 6. The impairment of cells might affect the release of HBV particles, which were increased.

In the present study, SCE-BC inhibited HBV antigen secretion. This role may take place at the transcription level (22). HBV enhancers, the transcriptional regulatory DNA fragments, may mediate the transcriptional suppression by binding several transcription factors. Alternatively, host's general transcription regulatory proteins, such as histone modification enzymes, epigenetic readers and transcription co-activators, are targeted to alter the transcription of a broad spectrum of host and viral genes (23). Therefore, the HBV mRNA level was determined in HepG2.2.15 cells in this study. Data demonstrated that in comparison to the control HBV mRNA levels were significantly decreased by SCE-BC. These results revealed that HBV antigen inhibition by SCE-BC was attributed to the specific inhibition of HBV mRNA expression. More work is needed to determine the mechanism of the transcriptional suppression.

In conclusion, the present study demonstrated that SCE-BC blocked HBV antigen secretion in vitro. This role of SCE-BC might take place at the transcription level. Moreover, SCE-BC had greater inhibitory activity with respect to HBeAg than to HBsAg. Since HBeAg promotes immune tolerance and persistent infection during HBV infection (24), the present results suggest that immune tolerance induced by HBeAg might be overcome by SCE-BC. Therefore, SCE-BC warrants further investigation.

Summary

This study sought to investigate the protective effect of an alternative medicine, Shufeng Jiedu Capsule, in acute lung injury and inflammation signaling pathways related to that action. Hematoxylin and eosin (HE) staining was used to observe pathological changes in rat lung tissue, arterial blood was subjected to blood gas analysis and lactic acid levels were determined, immunofluorescent staining for interleukin-1β (IL-1β) was performed, enzyme linked immunosorbent assay (ELISA) was used to detect biomarkers of the nuclear factor-kB (NF-κB) inflammation pathway including IL-1β and tumor necrosis factor α (TNF-α), biomarkers of the mitogen-activated protein kinase (MAPK) signal pathway including P-selectin, transforming growth factor β (TGF-β), keratinocyte-derived chemokine (KC), and C-Jun/AP-1 were measured, and real-time PCR was used to detect NF-κB mRNA. Results in rats with lipopolysaccharide-induced acute lung injury suggested that Shufeng Jiedu Capsule may increase the partial pressure of oxygen in lung tissue, decrease lactic acid levels, inhibit inflammatory factors such as IL-1β and TNF-α, and suppress the levels of P-selectin, TGF-β, KC, C-Jun/AP-1, and NF-κB mRNA. Thus, Shufeng Jiedu Capsule is a traditional medicine that may alleviate acute lung injury by suppressing the MAPK/NF-κB signaling pathway.

Keywords: Acute lung injury, Shufeng Jiedu Capsule, dexamethasone, rat model, MAPK/NF-κB signaling pathway

1. Introduction

H7N9 avian influenza, a disease caused by the H7N9 avian influenza virus, can lead to acute lung injury. In March 2013, H7N9 avian influenza was found in Shanghai and Anhui Province in China and recurred in eastern and southern China in early 2014. Human infection with the virus has resulted in a high mortality rate of about 20-30% according to recent data (1). Human infection with H7N9 avian influenza has received a great deal of attention from China’s Ministry of Health and the World Health Organization. In the early stages of H7N9 influenza, patients have flu-like symptoms such as a fever, coughing, and headaches. Some patients have more severe symptoms, such as a high fever that remains above 39°C, expiratory dyspnea, hemoptysis, and acute lung injury; patients usually die of acute respiratory distress syndrome caused by respiratory failure (2).

Acute lung injury (ALI) is characterized by acute hypoxemic respiratory failure with several potential causes, including trauma, shock, viruses, and bacterial endotoxins (3). ALI can lead to injury of alveolar epithelial cells and capillary endothelial cells and diffuse pulmonary interstitial and alveolar edema. When lung tissue is affected by a virus or bacterial endotoxin, G protein-coupled receptors (membrane proteins) in lung cells are activated. Cells are increasingly exposed to intracellular oxidative stress and the downstream
inflammatory pathway is triggered, leading to ALI (4,5).

Dexamethasone (DXMS) is a type of synthetic glucocorticoid and is a routine medication to control the inflammatory response (6). DXMS alleviates hypernomic inflammation and injury by inhibiting NF-xB activity. However, there is disagreement as to the clinical value of DXMS since it cannot improve prognosis in the early stages (7). Thus, only a small dose of DXMS is recommended to treat advanced cases of fibrosis. DXMS causes several adverse reactions such as decreased immune function, blood pressure and blood glucose fluctuations, hemorrhaging of the digestive tract, and femoral neck necrosis (8,9). Thus, there is an urgent need for an alternative in clinical settings.

Shufeng Jiedu Capsule (SFJDC) is a traditional Chinese medicine that is mainly used to treat upper respiratory tract infections such as the flu, swelling and pain in the throat, mumps, and strep throat (10). A previous study has suggested that SFJDC can inhibit viruses such as Adv-7, RSV, HSV-1, and the flu virus and bacteria such as Staphylococcus aureus, Staphylococcus epidermidis, and Pseudomonas aeruginosa (11). In China, SFJDC has been listed as drug to combat avian influenza. Studies have reported that active constituents of SFJDC such as resveratrol and quercetin may alleviate inflammation by suppressing the mitogen-activated protein kinase (MAPK)/nuclear factor-kB (NF-kB) signaling pathway (12-14). However, few studies have examined the effect of SFJDC on cellular signaling pathways. Thus, the current study sought to explore the effect of treatment with DMXS and SFJDC in rats with lipopolysaccharide (LPS)-induced ALI.

2. Materials and Methods

2.1. Materials

Endotoxin was purchased from Sigma Aldrich (St. Louis, MO, USA). SFJDC were purchased from Jieren Pharmaceutical (Anhui, China). A real-time PCR kit and enzyme linked immunosorbent assay (ELISA) kit for interleukin-1β (IL-1β) were purchased from Univ-Bio (Shanghai, China). ELISA kits for P-selectin, transforming growth factor β (TGF-β), tumor necrosis factor α (TNF-α), C-Jun/AP-1, and keratinocyte-derived chemokine (KC) were purchased from Shanghai United Cell Biotechnology Corporation (Shanghai, China).

2.2. Animals

Eighty specific-pathogen-free male Sprague-Dawley rats weighing 250 ± 20 g were purchased from Fudan University’s Animal Research Center (Shanghai, China). ALI model rats were induced by intraperitoneal injection of 10 mg/kg LPS. Rats were randomly divided into four groups: a saline control group, rats with LPS-induced ALI, rats with LPS-induced ALI that were treated with dexamethasone (DXMS), and rats with LPS-induced ALI that were treated with SFJDC. There were 20 rats in each group.

The saline control group and rats with untreated ALI were administered 2 mL/kg saline. Rats treated with DXMS were intraperitoneally injected with dexamethasone 5 mg/kg, and rats treated with SFJDC were intragastrically administered SFJDC 100 mg/kg. The above treatments were given once daily and continued for 7 days. On day 1, day 3, day 5, and day 7, rats were anesthetized with ether and sacrificed. Tissue specimens were taken from 5 random rats in each of the 4 groups. Arterial blood was collected and the lungs were removed. Tissue of the right lower lung was preserved in liquid nitrogen. The left lung was fixed in 40% paraformaldehyde and then sliced into paraffin sections. These paraffin sections were used in hematoxylin and eosin (HE) staining and confocal laser scanning microscopy (Leica TCS SP8, Solms, Germany) of IL-1β fluorescence.

2.3. ELISA assay for IL-1β, P-selectin, TGF-β, TNF-α, KC, and C-Jun/AP-1

The right lower lung was removed from liquid nitrogen, washed with cold saline, and dried with filter paper. One hundred mg of lung tissue was made into a homogenate with cold saline. ELISA was used to detect levels of IL-1β, P-selectin, TGF-β, TNF-α, KC, and C-Jun/AP-1 expression in this homogenate.

2.4. Real-time PCR detection of NF-κB mRNA

Total RNA was collected using Trizol (Gibco-BRL, Gaithersburg, USA). cDNA was prepared using a 1-step PCR kit (Promega, USA) and PTC-200 PCR device (MJ Research, USA). The primer sequence was as follows: rGAPD (5’-AGTGCAGCTCCTCTCATAG-3’) and 5’-CGTTGAACCTGCGGGAATG-3’. The primer had a melting temperature (Tm) of 59°C. Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) served as an internal reference. PCR products were analyzed using Quantity One software (Bio-Rad, Hercules, USA).

2.5. Confocal laser scanning imaging

Tissue slices were washed 3 times with PBS, fixed in methanol for 30 min, washed 3 times with PBS, denatured with HCl for 40 min, washed 3 times with PBS, blocked with sheep serum for 30 min, washed 3 times with PBS, and incubated with IL-1β monoclonal body overnight. Slices were washed 3 times with PBS and incubated with the secondary antibody. Confocal laser scanning microscopy (Leica TCS SP8, Solms, Germany) was used to observe fluorescence.

2.6. Statistical analysis
Data were analyzed using SPSS 18.0 software and are presented as the mean ± standard deviation (S.D.). A homogeneity of variance and a normal distribution were verified. Once data were found to have a homogeneity of variance and a normal distribution, one-way ANOVA was performed. If results were statistically significant, a pair-wise comparison was done using the least significant difference test. A $p < 0.05$ was considered statistically significant.

3. Results

3.1. Morphological changes in lung tissue

As shown in Figure 1, lung tissue from rats with untreated ALI had severe alveolar exudation, hemorrhaging, edema, small airway collapse, and necrosis of airway epithelial cells on day 1. Exudation and hemorrhaging were not noted in tissue from rats treated with DXMS and rats treated with SFJDC. Lung tissue retained its basic structure, and the inflammatory response was milder in rats treated with DXMS or SFJDC than in rats with untreated ALI. On day 3, more severe inflammation was noted in lung tissue from rats with untreated ALI with obvious exudation and destruction of alveolar structures. Rats treated with DXMS and rats treated with SFJDC also had inflammation but alveolar structures remained and inflammation was mild. Rats treated with SFJDC had milder inflammation than rats treated with DXMS. On day 5 and day 7, inflammation had subsided in all of the rats. The inflammatory response was much milder in rats treated with SFJDC.

3.2. Immunofluorescent staining for IL-1β

As shown in Figure 2, the saline control group had no obvious green fluorescence for IL-1β, indicating...
a very low level of IL-1β. Rats with untreated ALI had significant green fluorescence. Compared to the saline control group, rats treated with SFJDC and rats treated with DXMS had green fluorescence, indicating an increased level of IL-1β. Green fluorescence was markedly less intense than that noted in rats with untreated ALI, indicating that SFJDC and DXMS had decreased the level of IL-1β.

3.3. Blood gas analysis of arterial blood and determination of lactic acid levels

As shown in Figure 3, the partial pressure of oxygen remained between 107-113 mmHg in the saline control group. On day 1, day 3, day 5, and day 7, the partial pressure of oxygen increased gradually from 60 mmHg to 86 mmHg in rats with untreated ALI. The partial pressure of oxygen generally increased from 64 mmHg to 103 mmHg in rats treated with SFJDC and it increased slightly from 54 mmHg to 76 mmHg in rats treated with DXMS. These results indicate that rats treated with SFJDC had a higher partial pressure of oxygen than did rats with untreated ALI on day 5 and day 7. However, rats treated with DXMS had a lower partial pressure of oxygen than rats did with untreated ALI at these two times. On day 1, day 3, day 5, and day 7, the lactic acid level in the saline control group remained between 2.6-2.8 mmol/L. The lactic acid level ranged from 6.8 mmol/L to 3.8 mmol/L in rats with untreated ALI, from 5.7 mmol/L to 2.7 mmol/L in rats treated with SFJDC, and from 6.3 mmol/L to 4.4 mmol/L in rats treated with DXMS. SFJDC markedly reduced the level of lactic acid on day 3, day 5, and day 7 \((p < 0.05)\) in comparison to that in rats with untreated ALI. However, there was no evidence of a decrease in the level of lactic acid in rats treated with DXMS.

3.4. Results of ELISA detection of IL-1β, TNF-α, P-selectin, TGF-β, KC, and C-Jun/AP-1

As shown in Figure 4, ELISA was used to determine levels of IL-1β, TNF-α, P-selectin, TGF-β, KC, and C-Jun/AP-1 in each group at different times. The level of IL-1β remained between 300-325 pg/mL in the saline control group. The level of IL-1β ranged from 809 to 557 pg/mL in rats with untreated ALI, from 761 to 376 pg/mL in rats treated with SFJDC, and from 715 to 399 pg/mL in rats treated with DXMS. Compared to rats with untreated ALI, rats treated with SFJDC had an obvious decrease in the level of IL-1β on day 3, day 5, and day 7 \((p < 0.05)\). There were no significant differences in the level of IL-1β for rats treated with SFJDC and rats treated with DXMS. The level of TNF-α remained between 4.0-4.9 pg/mL in the saline control group. The level of TNF-α ranged from 15.5 to 12.8 pg/mL in rats with untreated ALI, from...
15.5 to 5.5 pg/mL in rats treated with SFJDC, and from 14.3 to 7.4 pg/mL in rats treated with DXMS. Compared to rats with untreated ALI, rats treated with SFJDC had an obvious decrease in the level of TNF-α on day 3, day 5, and day 7 (p < 0.05). There were no significant differences in the level of TNF-α for rats treated with SFJDC and rats treated with DXMS. The level of P-selectin remained between 442-451 pg/mL in the saline control group. The level of P-selectin ranged from 574 to 517 pg/mL in rats with untreated ALI, from 562 to 452 pg/mL in rats treated with SFJDC, and from 561 to 487 pg/mL in rats treated with DXMS. Compared to rats with untreated ALI, rats treated with SFJDC had an obvious decrease in the level of P-selectin on day 5 and day 7 (p < 0.05). The level of TGF-β remained between 253-585 pg/mL in rats with untreated ALI, from 562 to 452 pg/mL in rats treated with SFJDC, and from 561 to 487 pg/mL in rats treated with DXMS. Compared to rats with untreated ALI, rats treated with SFJDC had an obvious decrease in the level of TGF-β on day 5 and day 7 (p < 0.05). There were no significant differences in the level of TGF-β for rats treated with SFJDC and rats treated with DXMS. The level of KC ranged from 13,666 to 10,148 pg/mL in rats with untreated ALI, from 12,099 to 5,034 pg/mL in rats treated with SFJDC, and from 1,712 to 2,801 pg/mL in rats treated with DXMS. Compared to rats with untreated ALI, rats treated with SFJDC had an obvious decrease in the level of KC on day 3, day 5, and day 7 (p < 0.05). Compared to rats with untreated ALI, it increased from 1.5 (day 1) to 2.19 (day 3) and then decreased to 1.37 (day 7) in rats treated with SFJDC, and it increased from 2.57 (day 1) to 2.95 (day 3) and then decreased to 1.83 (day 7) in rats treated with DXMS. Compared to rats with untreated ALI, rats treated with SFJDC had an obvious decrease in the level of NF-κB mRNA on day 3, day 5, and day 7 (p < 0.05). There were no significant differences in the level of NF-κB for rats treated with SFJDC and rats treated with DXMS. The level of KC for rats treated with SFJDC and rats treated with DXMS. The level of C-Jun/AP-1 ranged from 3,426-3,676 pg/mL in the saline control group. The level of C-Jun/AP-1 in the saline control group ranged from 2,215-2,606 pg/mL in the saline control group. The level of C-Jun/AP-1 ranged from 574 to 517 pg/mL in rats with untreated ALI, from 562 to 452 pg/mL in rats treated with SFJDC, and from 561 to 487 pg/mL in rats treated with DXMS. Compared to rats with untreated ALI, rats treated with SFJDC had an obvious decrease in the level of C-Jun/AP-1 on day 3, day 5, and day 7 (p < 0.05). There were no significant differences in the level of C-Jun/AP-1 for rats treated with SFJDC and rats treated with DXMS.

3.5. Level of NF-κB mRNA expression

As shown in Table 1, the level of NF-κB mRNA expression in rat lung tissue was determined using real-time PCR and was analyzed using the 2−ΔΔCt method. The mean value of nucleic acid fluorescent intensity was first determined. The mean value for the control group was subtracted from the mean value for an experimental group, and the difference was squared. The resulting values reflected a relative change in mRNA expression. The level of expression remained at around 2.0 in the saline control group, it increased from 1.80 (day 1) to 5.99 (day 3) and then decreased to 3.14 (day 7) in rats with untreated ALI, it increased from 1.5 (day 1) to 2.19 (day 3) and then decreased to 1.37 (day 7) in rats treated with SFJDC, and it increased from 2.57 (day 1) to 2.95 (day 3) and then decreased to 1.83 (day 7) in rats treated with DXMS. Compared to rats with untreated ALI, rats treated with SFJDC had an obvious decrease in the level of NF-κB mRNA (p < 0.05).

4. Discussion

According to previous studies, DXMS may alleviate the inflammatory response by suppressing the MAPK/NF-κB signaling pathway. Numerous studies have indicated that the active constituents of SFJDC, such as resveratrol, quercetin, and other flavonoids, inhibit

the MAPK/NF-κB signaling pathway in several cell lines (Table 2) (15-21). The current study sought to investigate whether SFJDC could provide protection from ALI by inhibiting inflammatory signaling pathways.

NF-κB is a key factor in the inflammatory response and is involved in the development of ALI (22,23). When patients are affected by trauma, shock, a virus, or a bacterial endotoxin, the NF-κB signaling pathway is activated. Inflammatory cells such as neutrophils granulocytes and macrophages are subsequently triggered, inflammatory mediators such as IL-1β and TNF-α are released, and oxidative stress is promoted (24,25). IL-1β and TNF-α may serve as biomarkers of the NF-κB inflammatory pathway. A previous study using DXMS as a positive control determined levels of IL-1β and TNF-α to assess the protective effect of SFJDC in a rat model of LPS-induced ALI (26). Confocal laser scanning imaging revealed an obvious decrease in the levels of IL-1β in both rats treated with SFJDC and rats treated with DXMS compared to rats with untreated ALI. This finding suggests that SFJDC may alleviate inflammation by inhibiting IL-1β in the NF-κB signaling pathway. Real-time PCR indicated that expression of NF-κB mRNA was effectively suppressed in rats treated with SFJDC in comparison to that in rats with untreated ALI (p < 0.01). Thus, SFJDC may alleviate ALI by inhibiting the NF-κB-dependent inflammatory response.

MAPKs (also known as MAP kinases) are serine/threonine/tyrosine-specific protein kinases belonging to the CMGC (CDK/MAPK/GSK3/CLK) kinase group, and the P38δ MAPK receptor is expressed at high levels in lung tissue (27). MAPK phosphorylation is associated with activation of NF-κB in the inflammatory response (28). MAPKs function in stress, inflammation, tumor, cell growth, differentiation, apoptosis, and fibrosis. P-selectin, TGF-β, KC, and C-Jun/AP-1 are involved in the MAPK signaling pathway, and they may serve as biomarkers of the MAPK pathway (29-32). An ELISA assay revealed that rats treated with SFJDC had a more obvious decrease in the level of P-selectin, TGF-β, KC, and C-Jun/AP-1 in lung tissue in comparison to rats with untreated ALI (p < 0.01). This indicates that SFJDC may alleviate LPS-induced stress injury, decrease lung cell apoptosis, and protect lung tissue by inhibiting the MAPK signaling pathway.

The pathology of rat lung tissue was observed using HE staining. Like rats treated with DXMS, rats treated with SFJDC had a much milder inflammatory response and protected lung tissue. In conclusion, this study revealed that SFJDC alleviates LPS-induced inflammation in a rat model by suppressing the MAPK/NF-κB signaling pathway. Thus, SFJDC might serve as an alternative medication to inhibit inflammation in different organs and SFJDC has great potential for wide clinical use.

Summary
This study retrospectively analyzed Chinese publicly reported data on Human Immunodeficiency Virus/Acquired Immune Deficiency Syndrome (HIV/AIDS). The HIV/AIDS morbidity (1/100,000) and mortality (1/100,000) rates in China continually increased from 0.23 and 0.06 in 2004 to 1.53 and 0.69 in 2011, respectively. The AIDS case fatality rate decreased yearly from 53.57% in 2008 to 45.11% in 2011, and the fatality rate in rural areas (0.25-0.42%) was higher than that in cities (0.13-0.22%). The number of HIV/AIDS patients discharged from city-level hospitals increased from 329 in 2004 to 7,266 in 2011, and this number was higher than the number of similar patients discharged from county-level (rural) hospitals (the number of HIV/AIDS patients increased from 252 in 2004 to 5,957 in 2011). The factors contributing to these trends include: enhanced physician HIV/AIDS education regarding diagnosis, intervention, monitoring, testing, and treatment; improved safety of blood collection and use; and improved management of HIV/AIDS patients. Therefore, HIV/AIDS prevention and control in rural areas of China is the key to reducing HIV transmission and mortality in China.

Keywords: HIV/AIDS, clinical epidemiology, China

1. Introduction

Among infectious diseases in China, Acquired Immune Deficiency Syndrome (AIDS) has recently become the leading cause of death, and the number of AIDS-related deaths is significantly higher than that due to any other infectious disease (1). Epidemiological reports of Human Immunodeficiency Virus (HIV)/AIDS from the United States, Brazil, and South Africa have been published (2-6). At present, there are several regional reports on the incidence of HIV/AIDS in China (7-9), but national reports of the clinical epidemiology of HIV/AIDS are rare. Therefore, HIV/AIDS prevention and control poses a challenge in China due to the lack of complete and accurate information on the epidemiology of HIV/AIDS. The current study retrospectively analyzed the HIV/AIDS morbidity, mortality, and case fatality rates, as well as hospital discharges in China from 2004 to 2011, to determine the distribution and characteristics of the HIV/AIDS population and provide further information on and guidance for HIV/AIDS prevention and control in China and the rest of the world.

2. Materials and Methods

2.1. Data sources

Most of the data in this study were obtained from the "China Public Health Statistics Yearbook (2005-2012)." The number of patients hospitalized each year and treatment outcomes were obtained from the "Statistical Annual Report of Medical Service in China." Data regarding morbidity, mortality, and fatality rates of infectious diseases were obtained from Annual Statistics on Infectious Diseases that Must be Reported by Law in the "Chinese Public Health Statistical Yearbook." These data were collected from a total of 31 regions in China and excluded Hong Kong and Macao.
2.2. Definitions

Morbidity from infectious diseases that must be reported by law = number of cases of infectious diseases that must be reported by law/population × 100,000.

Mortality from infectious diseases that must be reported by law = number of deaths from infectious diseases that must be reported by law/population × 100,000.

Fatality rate from infectious diseases that must be reported by law = number of deaths from infectious diseases that must be reported by law/number of cases × 100%.

Age-specific mortality among males (females) = number of deaths among males (females) of a certain age group/average male (female) population of the same age group.

The number of discharged patients refers to the number of inpatients who were discharged from acute care hospitals.

Urban and rural area classification: urban areas include municipalities and prefecture-level cities while rural areas include counties and county-level cities, towns, and villages.

Urban and rural populations were calculated according to "Regulations on Statistical Classification of Urban and Rural Areas (draft)" released by the National Bureau of Statistics in 1999.

Population refers to the total number of living individuals within a certain area at a certain time point.

2.3. Statistical analysis

Data were analyzed using the Statistical Package for the Social Sciences (SPSS) version 19.0. A chi-square ($\chi^2$) test was performed, and the mean ± standard deviation (S.D.) was determined.

3. Results

3.1. HIV/AIDS in China

The HIV/AIDS morbidity, mortality, and fatality rates per year were first determined based on the total population of China for that year, and then the $p$ value was calculated using a Chi-square ($\chi^2$) test. The HIV/AIDS morbidity rate (1/100,000) and mortality rate (1/100,000) continually increased in China from 2004 to 2011 ($p < 0.01$). The AIDS fatality rate (%) increased from 2004 to 2008 and then decreased yearly from 2009 to 2011 ($p < 0.01$; Figure 1).

Statistical analysis of data from 31 regions in China from 2004 to 2011 indicated the following: i) The regions with the highest HIV/AIDS morbidity rates were Henan Province from 2004 to 2006, Guangxi Province from 2005 to 2011, and Yunnan Province from 2006 to 2011. ii) The regions with the highest HIV/AIDS mortality rates were Henan Province from 2004 to 2009, Yunnan Province from 2007 to 2011, and Guangxi Province from 2009 to 2011. iii) The areas with the highest HIV/AIDS fatality rates included Gansu Province (90.91%) in 2004, Jiangxi Province (66.13%) in 2005, Gansu Province (80%), and the Ningxia Autonomous Region (100%) in 2006, Henan Province in 2008, the Inner Mongolia Autonomous Region (100%) in 2009, Henan and Hainan provinces (100%) in 2010, and Hainan Province (72.92%) in 2011. Regions with low HIV/AIDS fatality rates included Tibet (0%) in 2007 and Beijing (12.68%) in 2008. In addition, the regions with HIV/AIDS morbidity and mortality rates above the national averages were Xinjiang, Sichuan, and Chongqing from 2009 to 2011 (Table 1), while Shanghai had an HIV/AIDS morbidity rate above the national average from 2010 to 2011.

3.2. HIV/AIDS mortality rate

The HIV/AIDS mortality rate among Chinese residents from 2004 to 2011: The HIV/AIDS mortality rate in rural areas was higher than that in urban areas of China. In addition, the HIV/AIDS mortality rate among men was higher than that among women ($p < 0.01$; Figure 2).

3.3. Hospitalization of HIV/AIDS patients in China

Distribution by age groups. HIV/AIDS patients discharged from Chinese hospitals from 2004 to 2011 fell primarily into three age groups: 15-44 years, 45-59 years, and 60 years and older. The proportion of HIV/AIDS patients who were younger decreased from 72.7% in 2004 to 55.5% in 2011, the proportion of middle-aged patients increased from 18.3% to 27.1%, and the proportion of elderly patients increased from 6.6% to 15% (Figure 3). Men accounted for the majority of HIV/AIDS patients among individuals aged 60 years and older ($p < 0.01$).

Differences between rural and urban areas. From 2004 to 2011, the number of HIV/AIDS patients discharged from city-level hospitals was higher than that of HIV/AIDS patients discharged from county-level (rural) hospitals ($p > 0.05$) (Figure 4).
4.1. HIV/AIDS morbidity and mortality rates in China are continuing to increase

The high HIV/AIDS morbidity rate in Henan Province was mainly due to the illegal selling of blood by poor donors (selling blood is illegal in China). This rate has decreased since 2007, as the government took great measures to crack down on the illegal blood trade (10). Guangxi and Yunnan are close to the Golden Triangle in Burma, where injectable drug use was once the main source of HIV transmission, but unprotected sex has recently become a major source of HIV transmission.

4.2. Discussion

HIV/AIDS morbidity and mortality rates in China have continued to increase. The high rate in Henan Province was due to the illegal selling of blood, while Guangxi and Yunnan have seen a shift to unprotected sex as the main transmission route. The government has taken significant actions to reduce the illegal blood trade, but the trend towards increased transmission via unprotected sex continues to be a concern.

Differences between HIV/AIDS patients in rural and urban areas

Rural areas of China are relatively poor, with high rates of drug use and unprotected sex. Low awareness of HIV/AIDS prevention and a lack of health care service are more common in rural areas than in urban areas. HIV/AIDS typically remains undetected until the late stage of the disease. Therefore, the HIV/AIDS fatality rate in rural areas is higher than that in urban areas. This also means that the HIV/AIDS fatality rate is higher among HIV/AIDS patients who live in the poor regions of China.

Although the number of hospitalized HIV/AIDS patients in China increased from 581 in 2004 to 13,223 in 2011, this only accounted for a small proportion of the HIV/AIDS patients in China, as the number of new cases in China in 2011 totaled 20,450 (1). Rural areas had fewer hospitalized HIV/AIDS patients than did cities.

Availability of HIV/AIDS specialists in China

The proportion of Chinese physicians specializing infectious diseases dropped from 2.4% in 2005 to 0.9% in 2011. A three-tier medical treatment system has been established in China where general hospitals are the principal care provider, specialized hospitals provide backup, and basic medical and health facilities are auxiliaries. In 2011, 39.04% of Chinese medical and health facilities were general hospitals and these facilities outnumber specialized hospitals by 6.75 to 1. In addition, 44.63% of practitioners worked in general hospitals. The proportion of medical practitioners caring for urban and rural populations in China differed, with 2.78 physicians per 1,000 individuals in urban areas and 0.96 physicians per 1,000 individuals in rural areas in 2011. There are 164 infectious disease hospitals and 9,307 practicing physicians in China in 2011, and 135 hospitals were located in cities while only 29 were located in rural areas. There were 10,219,397 visits for outpatient services compared to 662,258 hospitalizations. The number of urban HIV patients exceeded that of rural patients by 1.22-fold (1). Overall, the outlook for general hospitals is more hopeful than that for specialized hospitals in China.
A huge workload and low income are the main causes of the high rate of turnover for doctors working in infectious disease hospitals. Based on these data, China is clearly experiencing a severe shortage of physicians, particularly in rural areas where there is a higher demand for HIV/AIDS health care professionals.

4.5. Economic burden of HIV/AIDS care

The estimated number of HIV/AIDS patients in China was approximately 780,000 until the end of 2011; of these, only 154,000 were AIDS patients and 48,000 were newly discovered cases (14). That means that approximately 578,000 cases were undetected. The average annual income per person in 2011 was 23,979.2 RMB in urban areas of China and 9,833.1 RMB in rural areas. The hospitalization cost was 7,108.2 RMB per discharged HIV/AIDS patient in China in 2011 (1). The total hospitalization cost could be as high as 93,990,000 RMB when calculated on the basis of 13,223 hospitalized patients. If the total hospitalization cost is calculated on the basis of 154,000 HIV/AIDS patients, then it would be a sizable economic burden for China. The financial cost of HIV/AIDS treatment is also a major financial burden for individual patients, particularly for those from poor regions, as not all care is covered by the government.

Hospitalized HIV/AIDS patients in China are primarily in the age range of 15-44 years. These young patients tend to work far from home, being part of the migrant population in cities (10, 15). They may also transmit HIV to their sexual partners, many of whom might become pregnant. Not only are the life expectancy and quality of life of individuals with HIV affected, but many of their children become orphaned and represent a major societal burden (6,16-18).

The number of HIV/AIDS patients aged 60 years and older has increased. One reason is because many HIV/AIDS patients who were infected with HIV at a younger age have become older and fallen into this age group. In addition, male patients account for the majority of patients in this age group. Men over 60 still desire sex, regardless of whether they are from cities or rural areas. However, many of these individuals lack awareness of HIV prevention and rarely use condoms, thus increasing the rate of HIV infection (10-12).

4.6. Measures taken by the Chinese Government to improve HIV/AIDS care

The number of hospitalized HIV/AIDS patients is rather low in China and most of these patients receive treatment at city-level hospitals. This includes some rural patients who cannot receive appropriate treatment at local hospitals due to the lack of medical resources and poor economic conditions. Since the majority of HIV/AIDS patients live in poor rural areas of China, controlling HIV/AIDS morbidity and mortality rates in rural areas is difficult since county-level hospitals cannot provide appropriate diagnostic and treatment services. Therefore, the overall HIV/AIDS epidemic in China will be a challenge to control, and rural areas should be key targets for HIV/AIDS prevention and control in China. Public education of HIV prevention should be provided to increase awareness. The government's "Four Free and One Care" policy (free screening test, free treatment for poor AIDS patients, free schooling for orphans of AIDS patients, free counseling and antiretroviral therapy for HIV-infected pregnant women, and care and economic assistance to affected households) needs to be implemented in these areas. Long-distance medical services and knowledge sharing (19,20) are also keys to HIV/AIDS control in China, particularly in the poor regions.

The Chinese Government has directed great attention to the prevention and control of HIV/AIDS. Although problems such as the availability of many commercial and free anti-HIV medications remain because China is a developing country, the Government has taken important measures to prevent and control HIV/AIDS in China. These efforts include establishing the Classification and Diagnostic Criteria of HIV/AIDS for Adolescents and Adults and publishing materials such as the "National Manual for Free Antiretroviral Treatment of HIV/AIDS" and the "Guidelines on Diagnosis and Treatment of HIV/AIDS." In January 2012, the first 58 clinical pathways for diagnosis and treatment of HIV/AIDS and related diseases in China were recommended by the Clinical Pathway Pilot Project of the Ministry of Health of the People's Republic of China (21). At present, there are a total of 32 approved anti-HIV drugs from six major classes available in China. The recommended standard protocols include: highly active antiretroviral therapy (HAART): two nucleotide reverse transcriptase inhibitors (NRTIs) plus one NNRTI; or two NRTIs plus a boosted protease inhibitor (PI) (with ritonavir); and if necessary, combinations of three NRTIs. Since the availability of anti-HIV drugs in China is limited, the first-line regimen for patients who have not received any prior anti-virus medications is zidovudine (AZT) or stavudine (d4T) plus lamivudine (3TC) plus nevirapine (NVP) or efavirenz (EFV). For patients who fail to respond to the first-line regimen, the second-line regimen is tenofovir disoproxil fumarate (TDF) (abacavir [ABC] for children) plus 3TC + r (22). In January 2012, the "Notice regarding Publication of China's 12-Year Action Plan to Contain and Control HIV/AIDS" was issued by the General Office of the State Council of the People's Republic of China. This official document stated that the number of new HIV/AIDS cases should decrease by 25% and the fatality rate should decrease by 30% at the end of 2015 compared to 2010, and the total number of HIV/AIDS
patients should be less than 1,200,000 (23). Local
governments at various levels are required to expand
HIV/AIDS education and intervention, increase the
safety of blood collection and use to prevent iatrogenic
transmission, expand HIV/AIDS monitoring, testing,
and treatment, improve services for and management
of HIV/AIDS patients, and provide classification
guidelines. Therefore, the Chinese Government is
clearly determined to prevent and control HIV/AIDS.

In conclusion, information regarding the
epidemiologic features of HIV/AIDS in China and early
outcomes of government policies is the key to controlling
the HIV/AIDS pandemic in China. This information
can help with HIV/AIDS prevention and control around
the world. Effective measures to control the HIV/AIDS
pandemic in China include taking additional measures
to surveil and monitor HIV infection among the migrant
worker population in cities, among men over age 60,
and in poor regions with high HIV/AIDS morbidity
rates (10,12,24-25).

Stroke volume variation fail to predict fluid responsiveness in patients undergoing pulmonary lobectomy with one-lung ventilation using thoracotomy

Qiang Fu*, Feng Zhao*, Weidong Mi**, Hong Zhang

Department of Anesthesiology, General Hospital of PLA, Beijing, China.

Summary

The purpose of this study was to investigate the ability of stroke volume variation (SVV) to predict fluid responsiveness in patients undergoing pulmonary lobectomy with one-lung ventilation (OLV). Thirty patients intubated with double-lumen tube were scheduled for a pulmonary lobectomy requiring OLV for at least 1 hour under general anesthesia. Hemodynamic variables including heart rate, mean arterial pressure, cardiac index (CI), stroke volume index (SVI), central venous pressure (CVP) and SVV were measured before and after volume expansion (VE) (8 mL/kg of 6% hydroxyethyl starch). Fluid responsiveness was defined as an increase in CI ≥ 10% after VE. Of the 30 patients, 16 (53%) were responders and 14 (47%) were nonresponders to intravascular VE. There were significant increases of CI, SVI in responders after VE (p < 0.01), but there were no significant changes in SVV in responders and nonresponders (p > 0.05). The baseline value of SVV, CVP, CI and SVI did not correlate significantly with ΔCI (p > 0.05). The area under the Receiver Operating Characteristic (ROC) curve were 0.507 for SVV (95% confidence interval, 0.294-0.720) and 0.556 for CVP (95% confidence interval, 0.339-0.773), neither was able to predict fluid responsiveness with sufficient statistical power. SVV measured by the Vigileo-FloTrac system was not able to predict fluid responsiveness in patients undergoing pulmonary lobectomy with OLV after thoracotomy.

Keywords: Stroke volume variation, open-chest condition, fluid responsiveness, thoracotomy

1. Introduction

Lung-isolation techniques are primarily designed to facilitate One-Lung Ventilation (OLV) in patients undergoing thoracic, cardiac, mediastinal or esophageal procedures involving the chest cavity. It is essential to maintain optimal organ perfusion by appropriate fluid infusion to achieve the balance between preventing fluid overload and optimizing organ perfusion (1). Preload assessment is crucial to guide fluid therapy during thoracic surgery procedures. However, determining left ventricular preload in the clinical routine is particularly difficult during surgery. Filling pressures like central venous pressure (CVP) and pulmonary capillary wedge pressure (PCWP) are normally used as parameters of right and left heart preload. But these static indicators have been shown to be poor predictors of fluid responsiveness (2).

A recent Vigileo/FloTrac system (Edwards Lifescience, LLC, Irvine, CA, USA) allows for continuous monitoring of the cardiac output (CO) based on pulse contour analysis and of the respiratory variations in stroke volume (SVV) based on the analysis of the systemic arterial pressure wave. Stroke volume variation (SVV) is a parameter derived from changes in SV that is dependent on mechanical ventilation and has been found useful for predicting volume response in mechanically ventilated patients during perioperative phase (3,4). Only one study reported that SVV could predict fluid during OLV with PEEP in patients undergoing thoracoscopic lobectomy by using Vigileo system (5). However, all lobectomies in this study were performed under thoracoscopy in the same way. Since SVV during

OLV could be affected by the surgical procedure, it is still unknown whether SVV could predict fluid responsiveness during OLV with the chest open via a thoracotomy. The aim of this study was to examine the suitability of the established parameter of CVP and especially the new parameter of SVV to predict changes in cardiac index (CI) in patients undergoing pulmonary lobectomy with OLV after thoracotomy.

2. Materials and Methods

2.1. Patients characteristics

This prospective study was approved by institutional review board of General Hospital of PLA. All patients gave informed consent. From October 2009 to July 2011, a total of 33 patients received a pulmonary lobectomy with OLV and intraoperative infusion with colloids under general anesthesia. All patients were diagnosed with lung cancer preoperatively by computerized tomography (CT) and/or magnetic resonance imaging (MRI). Exclusion criteria applied to patients younger than 18 yr, with fibrillation atrial or intracardiac shunt.

2.2. Anesthesia and one-lung ventilation

After the patient arrived in the operating room, routine monitoring including pulse oxymetry, three-lead electrocardiogram and non-invasive arterial pressure was applied. Anesthesia was induced with i.v. bolus administration of fentanyl (3-5µg/kg), and propofol (1.5-2 mg/kg) 2 min later. Following loss of consciousness, orotracheal intubation was facilitated with rocuronium (0.6-0.9 mg/ kg). After anesthesia induction, a double-lumen endo-bronchial tube (Tyco Healthcare, Argyle, Mansfield, MA, USA) was inserted and the position was confirmed by fiberoptic bronchoscopy, the airway pressure was kept at 25-35 cm H2O. With the proper position of securing the airway, a radial arterial catheter (REFRA-04220, Arrow international Inc., Reading, PA, USA) was inserted and a central venous catheter (ES-04301, Arrow international Inc., Reading, PA, USA) was placed through right internal jugular vein. All pressure transducers were zeroed at midaxillary line to ambient pressure and initial pressures were recorded with the patient in the supine position. After changing the patient's position to lateral decubitus, all pressure transducers were re-positioned at the same value of initially measured pressures in the supine position. Anaesthesia was maintained with target controlled infusion (TCI) of propofol (2-4 µg/mL) and continuous infusion of remifentanil (0.3-0.8 µg/kg/min) with bispectral index (BIS, Aspect 1000™, Aspect Medical Systems Inc., Natick, MA, USA) kept between 40 and 50. Following the initiation of OLV, patients were ventilated with a tidal volume of 8 mL/kg ideal body weight, a ventilation rate of 12 cycle/min, inspired oxygen fraction (FIO2) was 1.0 and no PEEP was applied.

2.3. Hemodynamic monitoring

A dedicated transducer (FloTrac™, Edwards Lifesciences, LLC, Irvine, CA, USA) was connected to the radial arterial line on one side and to the Vigileo System (Vigileo™ Edwards Lifesciences, LLC, Irvine, CA, USA) on the other side. The system enables the continuous monitoring of SV, stroke volume index (SVI), CO, CI and SVV without calibration. The Vigileo (Software version 1.14) analyses the pressure waveform 100 times per second (100 Hz), and performs its calculations on the most recent 20 s data. CI obtained with this device was recorded and used to discriminate responder and non-responder patients after VE. SVV is calculated as the variation of beat-to-beat SV from the mean value during the most recent 20 s data and is displayed continuously. At each step of the study protocol, the following were recorded simultaneously: heart rate (HR), systolic arterial pressure, mean arterial pressure (MAP), diastolic arterial pressure and end-expiratory central venous pressure (CVP).

2.4. Study protocol

This study assessed the capability of SVV to predict fluid responsiveness during OLV. The study was started after finishing chest opening (thoracotomy) and collapsing one lung completely. During OLV, values of HR, MAP, CVP, SV/SVI, CO/CI and SVV were measured before (T0) and 30 min (T1) after fluid loading. Intraoperative infusion with 8 mL/kg of 6% hydroxyethyl starch was started when deemed necessary by the attending anesthesiologists, and completed in 30 min. Hemodynamic measurements were performed before, and within 30s after volume expansion (VE) without stimulation. All patients were studied at 30 min after starting OLV. During the VE, ventilator settings were kept consistent. If obvious hemorrhage (volume > 100 mL) or arrhythmias happened, the infusion protocol would be terminated and patient would be treated accordingly.

2.5. Statistical analysis

All data are presented as mean ± S.D. Distribution normality was assessed using Kolmogorov–Smirnov test. Changes in haemodynamic measures induced by VE were assessed using one-way analysis of variance (ANOVA). Patients were divided into two groups according to the percent increase in CI after intravascular VE. Responders were defined as patients demonstrating an increase in CI ≥ 10% after intravascular VE and non-responders as patients whose CI changed < 10%. Receiver operating characteristic
3.4. Dynamic indices and static indices to predict fluid responsiveness

The overall performance for SVV and CVP in predicting the responsiveness of the stroke volume to intravascular VE was evaluated by constructing ROC curves (Figure 1). The area under the ROC curve was 0.507 for SVV (95% confidence interval, 0.294-0.720), the area under the ROC curve was 0.556 for CVP (95% confidence interval, 0.339-0.773). The ROC analysis showed that both SVV and CVP failed to predict fluid responsiveness in patients undergoing pulmonary lobectomy with OLV. Diagonal segments are produced by ties.

Values are mean ± S.D. HR, heart rate; MAP, mean arterial pressure; CI, cardiac output index; CVP, central venous pressure; SVI, stroke volume index; SVV, stroke volume variation. p1, volume expansion value vs. baseline value in non-responders; p2, baseline value in responders vs. baseline value in non-responders; p3, volume expansion value vs. baseline value in responders.

(ROC) curves were generated for SVV, SVI, CI, CVP and MAP. The areas under the ROC curves by varying the discriminating threshold for each parameter were calculated and compared according to the method described by Hanley and McNeil (6). Threshold value for each parameter was determined by considering values that yielded the greatest sensitivity and specificity. Pearson’s test was used to test correlation. A p-value less than 0.05 was considered as statistically significant. All statistic analysis was performed using SPSS 15.0 software (SPSS Inc, Chicago, IL, USA).

3. Results

3.1. Patients selection

Thirty-three patients were initially included. Among them, three patients were excluded from analysis because of arrhythmia (two patients; one had ventricular premature contraction, one had atrial fibrillation) or obvious hemorrhage (one patient; bleeding > 100 mL during volume loads) during the protocol. Thirty patients in this study consisted of 21 males and 9 females from 47 to 58-year-old (mean age, 52.4 ± 4.7 year). There was no case requiring the administration of vasoactive agents during volume loading, BP and HR were kept in normal range.

3.2. Changes in hemodynamic variables after volume expansion

Hemodynamic measurements in the responders and nonresponders at baseline and after VE are given in Table 1. After VE, no significant changes were found in the nonresponders, while in the responders, there were significant changes of CI (from 2.7 ± 0.6 to 3.5 ± 0.7 l/min/m²; p = 0.001), SVI (39.9 ± 15.2 to 51.6 ± 15.8 mL/m²; p = 0.008). At the same time we observed no significant changes in both SVV and CVP in responders. Before VE, there was no difference in CI, SVI, CVP, MAP and SVV at baseline (Table 1).

3.3. Fluid responsiveness to fluid therapy

There were no significant correlations between baseline values of CVP, MAP, SVI, CI and the percent change in CI after fluid expansion (r = -0.213, p = 0.114; r = 0.011, p = 0.954; r = -0.202, p = 0.294; r = -0.123, p = 0.517, respectively). And the baseline value of SVV also did not correlate significantly with the change in CI induced by fluid expansion (r = -0.171, p = 0.367).

3.4. Dynamic indices and static indices to predict fluid responsiveness

The overall performance for SVV and CVP in predicting the responsiveness of the stroke volume to intravascular VE was evaluated by constructing ROC curves (Figure 1). The area under the ROC curve was 0.507 for SVV (95% confidence interval, 0.294-0.720), the area under the ROC curve was 0.556 for CVP (95% confidence interval, 0.339-0.773). The ROC analysis showed that both SVV and CVP failed to predict fluid responsiveness with sufficient statistical power in patients undergoing pulmonary lobectomy with OLV. There was no significant difference in the area under ROC curves between SVV and CVP.
4. Discussion

OLV is necessary in a variety of thoracic surgery to collapse one lung for surgical procedure. Several studies have demonstrated that SVV could predict fluid responsiveness in two-lung mechanically ventilated patients, and more efficiently than CI, CVP, MAP, which is in accordance with increasing evidence that static preload indicators are not suited for functional hemodynamic monitoring (3,4,7). Only one study evaluated the ability of SVV to predict fluid responsiveness in patients undergoing OLV, and they found that SVV measured by the Vigileo-FloTrac system was able to predict fluid responsiveness in patients undergoing surgery with OLV with acceptable levels of sensitivity and specificity. Of note, all surgeries were performed under thoracoscopy in the same way (5). With the chest opening via thoracotomy, whether SVV derived from Vigileo-FloTrac system could predict fluid responsiveness in patients with OLV is still unknown. In the present study, we found that SVV measured by the Vigileo-FloTrac system was not able to predict fluid responsiveness in patients undergoing pulmonary lobectomy with OLV after thoracotomy.

Several studies have found that the dynamic volume responsive measurements like SVV and pulse pressure variation (PPV) obtained with PICCO system may be more suitable for monitoring the volume status of patients particularly under open-heart conditions during cardiac surgery and especially after sternotomy (8,9). Conversely, the others found that SVV and PPV were unable to predict fluid responsiveness in open chest condition (10,11). It has been shown that opening the chest via a sternotomy may result in an increase in CI and a decrease in SVV (9,10). The ventilated lung is actually not open to the atmosphere because its pleura are still intact and the mediastinum separates lungs from the atmosphere after sternotomy. But with the chest opening by thoracotomy, much of the pressure generated by the ventilator would not be transmitted to the pulmonary vessels but rather to the atmosphere (5). So SVV could not be predictive of fluid responsiveness in open-chest condition after thoracotomy.

Positive intrathoracic pressure following mechanical ventilation induces a reduction in left ventricular preload. This is reflected by variations in the SV. These variations during a defined interval have proven to be useful parameters of cardiac preload (12). But the ventilatory issues, such as tidal volume (13), positive end-expiratory pressure (14), and chest and lung compliance (15) may also have effects on SVV. SVV could predict fluid responsiveness in patients undergoing thoracoscopic lobectomy during OLV only when tidal volume is at least 8 mL/kg (13) and with PEEP (14). Another study showed that PPV could predict fluid responsiveness in patients who received protective OLV with tidal volume of 6 mL/kg, FiO2 of 0.5 and positive end-expiratory pressure (PEEP) of 5 cm H2O for lung surgery using thoracotomy, but not in patients who received conventional OLV with tidal volume of 10 mL/kg, FiO2 of 1.0 and no PEEP (16). In this study, OLV was started with a tidal volume of 8 mL/kg, FiO2 of 1.0 and no PEEP was applied. But during OLV, if the same tidal volume is applied, the ventilated lung is exposed to double the tidal volume of two-lung ventilation. This could increase right ventricular afterload and exaggerate the cyclic variation in stroke volume (17). In addition, the venous return could be influenced by the mechanical ventilation under chest opening due to the decrease in chest compliance and airway pressure. Previous studies have showed that SVV could predict fluid responsiveness in patients undergoing OLV only when tidal volume is at least 8 mL/kg (13), so in this study tidal volume was set as 8mL/kg, which had been used previously in two-lung ventilation (3,4) or one-lung ventilation (13).

Mechanical ventilation method, hypoxic pulmonary vasoconstriction in the non-ventilated lung and significant pulmonary arteriovenous shunt amount through the non-ventilated lung can influence the predictive value of SVV for fluid responsiveness, regardless of the patient's preload state. Due to pulmonary vascular resistance increase induced by hypoxic pulmonary vasoconstriction in non-ventilated lung, the blood flowed to the ventilated-side lung (18). During OLV, there is a 20-30% shunt through the non-ventilated lung even with optimal management. This shunt amount does not contribute to the generation of SVV because there is no cyclic change of intra-thoracic pressure in the non-ventilated lung (19). The results showed that SVV before the fluid challenge in both responders and nonresponders was fairly normal, we speculated that SVV was mainly associated with pulmonary flow distribution, did not correlate positively with tidal volume. The results of our study indicate that SVV failed to predict fluid responsiveness in patients undergoing pulmonary lobectomy with OLV after thoracotomy.

Some limitations of our study should be noted. Firstly, we measured CO with Vigileo-FloTrac system, but not a calibrated thermodilution CO monitor. Although thermodilution is considered as the clinical standard method to measure CO, but CO measured by Vigileo-FloTrac system correlated well with that measured by thermodilution. And due to the cost-effect, we did not prefer a calibrated thermodilution CO monitor or transesophagus echocardiograph. Secondly, we did not estimate shunt fraction, so could not draw a conclusion whether the less shunt fraction contributes to the bigger SVV that can predict fluid responsiveness. Thirdly, we could have compared two different ventilation strategies (i.e. lung-protective and conventional) to investigate SVV as a predictor of fluid
responsiveness during one-lung ventilation for lung surgery using thoracotomy, whether a clinically more relevant lung protective ventilation strategy would have yielded different results.

In conclusion, we evaluated the capability of SVV in predicting fluid responsiveness in patients receiving OLV. It was found that SVV measured by the Vigileo-FloTrac system was not able to predict fluid responsiveness in patients undergoing pulmonary lobectomy with OLV after thoracotomy.

1. Introduction

Psoriasis is a chronic inflammatory dermatosis of the skin affecting as many as 1-2% of Caucasian and 0.02-0.1% of Japanese people (1). Among them, some cases are thought to be accompanied with arthritis. Psoriatic arthritis is different from rheumatoid arthritis (RA) in terms of its predilection for the distal interphalangeal joints and negative rheumatoid factors (RF), and therefore is included in seronegative spondyloarthropathy. The arthritis is associated with cutaneous psoriasis in more than 90% of cases, and is preceded by the cutaneous lesion in 75% cases (2). Though treatment with monoclonal antibodies against tumor necrosis factor (TNF) (e.g. infliximab and adalimumab) or soluble TNF receptor (etanercept) have been in clinical use recently, the delay of treatment may result in the reduced quality of life and the severe deformities resembling the joint changes seen in RA. Therefore, the early detection and treatment of arthritis is necessary in psoriasis patients, and it is important to identify the pathological triggers of the arthritis. Until today, genetic factors, mechanical stimulations, infections, drugs, and immunologic factors are reported as triggers of psoriatic arthritis (2). Here, we report a female case with psoriasis whose arthritis may be triggered by the delivery.

2. Case reports

A 37-year-old Japanese female visited our hospital, for the treatment of the eruption and arthritis. There was no record of similar conditions in her family history. She had been diagnosed as having psoriasis vulgaris more than 20 years ago, and treated with corticosteroid ointments. She had never had arthralgia. She got her first child 3 months before the first visit, without any problems related to the delivery. However, she started to complain of arthralgia after the delivery, and the arthritis as well as the eruption worsened gradually. On physical examination, the patients had the skin lesions in the trunk and extremities. The each lesion was well-demarcated, erythematous plaque covered by silver-white scales (Figure 1). Neither pustules nor nail changes were observed. She could not stand up by herself because of her joint swelling and pain, which was present in finger, wrist, elbow, knee, and ankle joints.

As laboratory findings, the white blood cell (WBC) count and C-reactive protein (CRP) levels was slightly increased at 9,000/uL and 2.07 mg/dL, respectively. Antinuclear antibody or anti-cyclic citrullinated peptide (ACP) were not detected. Therefore, we diagnosed her case as psoiriatic arthritis due to the postpartum period.
Figure 1. Well-demarcated, erythematous plaques covered by silver-white scales in the back (a), upper arm (b), hands (c), and thighs (d).

Figure 2. 99mTc-MDP bone scintigraphy showing the increased uptake in finger, wrist, elbow, knee, and ankle joints.

Figure 3. Haematoxylin and eosin (H&E) staining of biopsy specimen from cutaneous lesion.
peptide (CCP) antibody was not detected. RF was also negative (7 IU/mL, normally < 20 IU/mL), and the serum level of matrix metalloproteinase (MMP)-3 was not increased (32.1 ng/mL, normally < 59.7 ng/mL). Laboratory results of other blood cell counts, blood chemistry analysis (including serum albumin, p-glucose or HbA1c), urinalysis, and chest radiography were within normal limits. Bone scintigraphy showed increased uptake in multiple joints (Figure 2), which were identical to the swollen and painful joints.

A skin biopsy from the affected area revealed acanthosis, hypogranulosis and extensive overlying parakeratotic scale in the epidermis. Perivascular infiltration of neutrophils and lymphocytes in the dermis was also seen (Figure 3).

Based on the findings of blood examination, bone scintigram and skin biopsy, she was diagnosed as having psoriasis and postpartum development of arthritis. Her Psoriasis Area and Severity Index (PASI) of the cutaneous lesion, DAS28-CRP and visual analogue scale (VAS) of the arthritis was 22.6, 3.9, and 60, respectively.

The patient was treated with infliximab immediately. After three times of administration, her eruption and arthritis have disappeared completely (Figure 4). The PASI and VAS was also improved dramatically as shown in Figure 5.

3. Discussion

Though the aetiology of psoriasis and psoriatic arthritis is multifactorial, one of the most likely pathogenic agents may be T cell (2). This suggestion is supported by many clinical studies for the treatment of psoriasis and psoriatic arthritis: e.g. the clinical efficacy of cyclosporin, a highly selective antagonist of T-cell proliferation and activation (2). Psoriasis has been regarded as the Th1-mediated disease like RA and Crohn disease (2-5). However, in the last few years, Th17, a new subset of CD4 T cells, has been identified, based on their production of IL-17 (6). There are many reports that indicate IL-17 is associated with the pathogenesis of psoriasis (7). In addition, it was reported that regulatory T cells (Treg), which suppress CD4 helper T cells, are impaired in many autoimmune diseases (8). Psoriatic Treg have also been found to defect the activity, which may result in the auto-reactive T cell activation and contribute to the pathogenesis for psoriasis (9). Taken together, in psoriasis and psoriatic arthritis, Th1 and Th17 should be predominant rather than Th2 and Treg, like RA.

On the other hand, although the change of immune system during pregnancy has not been fully clarified,
many studies have reported a predominant Th2/Treg-type immunity and a suppressed Th1/17-type immunity during normal pregnancy (10). These immunological changes seem to be necessary for successful pregnancy, because the predominance of Th1/17-type immunity over Th2/Treg-type immunity is observed in abortion patients (10). Estrogens and progesterone are known to inhibit Th1 immune responses including TNF-α and IL-12 production, while induce Th2 immune responses like IL-10 and IL-4 production (11). These hormones are significantly increased during pregnancy in comparison with the postpartum period. In addition, during pregnancy, Th1-type immunity is well controlled to avoid its overstimulation, probably due to the suppression by Treg, which are observed to increase in decidua (11). Furthermore, the level of IL-17 in normal pregnancy is lower than that in non-pregnancy, and Th17 is thought to be inhibited in the former condition (12). Taken together, in pregnancy, Th2/Treg-type immunity should be predominant over Th1/Th17-type immunity by the above changes in the hormones and cytokines, and the subsequent rebound of Th1/Th17 may occur after delivery.

The above notions suggest that immune tolerance may diminish in the postpartum period, which may alter the susceptibility to autoimmune diseases including RA. Actually, postpartum onset of RA by the Th1/Th17 activation has been well described (13). On the other hand, psoriasis is known to be one of the diseases which are improved during pregnancy (14). Furthermore, there is a very old report that states 6 of 20 psoriasis patients developed arthritis during postpartum period (15). Since then, however, there have been no reports describing similar cases. Our case is the second to suggest that the changes in immune balance after delivery may be the newly described trigger of arthritis in female patients with psoriasis. From this point of view, female patients should be followed-up carefully during postpartum period against the occurrence of arthritis.

Recent papers have shown that serum IL-17 level is reduced and Treg level is increased after infliximab treatment in psoriasis (16,17). As the limitation of the paper, because blood samples of the patient were not collected, we could not perform time course measurement of IL-17 levels and the number or activity of Treg before and during the treatment with infliximab, which may support our hypothesis. To confirm the immunologic mechanism in female patients with psoriatic arthritis during pre/postpartum period, further studies are needed in a large number of patients in the future.

Guide for Authors

1. Scope of Articles

BioScience Trends is an international peer-reviewed journal. BioScience Trends devotes to publishing the latest and most exciting advances in scientific research. Articles cover fields of life science such as biochemistry, molecular biology, clinical research, public health, medical care system, and social science in order to encourage cooperation and exchange among scientists and clinical researchers.

2. Submission Types

Original Articles should be well-documented, novel, and significant to the field as a whole. An Original Article should be arranged into the following sections: Title page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments, and References. Original articles should not exceed 5,000 words in length (excluding references) and should be limited to a maximum of 50 references. Articles may contain a maximum of 10 figures and/or tables.

Brief Reports definitively documenting either experimental results or informative clinical observations will be considered for publication in this category. Brief Reports are not intended for publication of incomplete or preliminary findings. Brief Reports should not exceed 3,000 words in length (excluding references) and should be limited to a maximum of 4 figures and/or tables and 30 references. A Brief Report contains the same sections as an Original Article, but the Results and Discussion sections should be combined.

Reviews should present a full and up-to-date account of recent developments within an area of research. Normally, reviews should not exceed 8,000 words in length (excluding references) and should be limited to a maximum of 100 references. Mini reviews are also accepted.

Policy Forum articles discuss research and policy issues in areas related to life science such as public health, the medical care system, and social science and may address governmental issues at district, national, and international levels of discourse. Policy Forum articles should not exceed 2,000 words in length (excluding references).

Case Reports should be detailed reports of the symptoms, signs, diagnosis, treatment, and follow-up of an individual patient. Case reports may contain a demographic profile of the patient but usually describe an unusual or novel occurrence. Unreported or unusual side effects or adverse interactions involving medications will also be considered. Case Reports should not exceed 3,000 words in length (excluding references).

News articles should report the latest events in health sciences and medical research from around the world. News should not exceed 500 words in length.

Letters should present considered opinions in response to articles published in BioScience Trends in the last 6 months or issues of general interest. Letters should not exceed 800 words in length and may contain a maximum of 10 references.

3. Editorial Policies

Ethics: BioScience Trends requires that authors of reports of investigations in humans or animals indicate that those studies were formally approved by a relevant ethics committee or review board.

Conflict of Interest: All authors are required to disclose any actual or potential conflict of interest including financial interests or relationships with other people or organizations that might raise questions of bias in the work reported. If no conflict of interest exists for each author, please state "There is no conflict of interest to disclose".

Submission Declaration: When a manuscript is considered for submission to BioScience Trends, the authors should confirm that 1) no part of this manuscript is currently under consideration for publication elsewhere; 2) this manuscript does not contain the same information in whole or in part as manuscripts that have been published, accepted, or are under review elsewhere, except in the form of an abstract, a letter to the editor, or part of a published lecture or academic thesis; 3) authorization for publication has been obtained from the authors’ employer or institution; and 4) all contributing authors have agreed to submit this manuscript.

Cover Letter: The manuscript must be accompanied by a cover letter signed by the corresponding author on behalf of all authors. The letter should indicate the basic findings of the work and their significance. The letter should also include a statement affirming that all authors concur with the submission and that the material submitted for publication has not been published previously or is not under consideration for publication elsewhere. The cover letter should be submitted in PDF format. For example of Cover Letter, please visit http://www.biosciencetrends.com/downcentre.php (Download Centre).

Copyright: A signed JOURNAL PUBLISHING AGREEMENT (JPA) form must be provided by post, fax, or as a scanned file before acceptance of the article. Only forms with a hand-written signature are accepted. This copyright will ensure the widest possible dissemination of information. A form facilitating transfer of copyright can be downloaded by clicking the appropriate link and can be returned to the e-mail address or fax number noted on the form (Please visit Download Centre). Please note that your manuscript will not proceed to the next step in publication until the JPA Form is received. In addition, if excerpts from other copyrighted works are included, the author(s) must obtain written permission from the copyright owners and credit the source(s) in the article.

Suggested Reviewers: A list of up to 3 reviewers who are qualified to assess the scientific merit of the study is welcomed. Reviewer information including names, affiliations, addresses, and e-mail should be provided at the same time the manuscript is submitted online. Please do not suggest reviewers with known conflicts of interest, including participants or anyone with a stake in the proposed research; anyone from the same institution; former students, advisors, or research collaborators (within the last three years); or close personal contacts. Please note that the Editor-in-Chief may accept one or more of the proposed reviewers or may request a review by other qualified persons.

Language Editing: Manuscripts prepared by authors whose native language is not English should have their work proofread by a native English speaker before submission. If not, this might delay the publication of your manuscript in BioScience Trends.

The Editing Support Organization can provide English proofreading, Japanese-proofreading, and Chinese-English translation services to authors who want to publish in BioScience Trends and need assistance before submitting a manuscript. Authors can visit this organization directly at http://www.iacnhr.com/iac-esosupport.php?lang=en. IAC-ESO was established to facilitate manuscript preparation by researchers whose native language is not English and to help edit works intended for international academic journals.

4. Manuscript Preparation

Manuscripts should be written in clear, grammatically correct English and submitted as a Microsoft Word file in a single-column format. Manuscripts must be paginated and typed in 12-point Times New Roman font with 24-point line spacing. Please do not embed figures in the text. Abbreviations should be used as little as possible and should be explained at first mention unless the term is a well-known abbreviation (e.g. DNA). Single words should not be abbreviated.

Title Page: The title page must include 1) the title of the paper (Please note the title should be short, informative, and contain the major key words); 2) full name(s) and affiliation(s) of the author(s); 3) abbreviated names of the author(s); 4) full name, mailing address, telephone/fax numbers, and e-mail address of the corresponding author; and 5) conflicts of interest (if you have an actual or potential conflict of interest to disclose, it must be included as a footnote on the title page of the manuscript; if no conflict of
interest exists for each author, please state "There is no conflict of interest to disclose"). Please visit Download Centre and refer to the title page of the manuscript sample.

Abstract: The abstract should briefly state the purpose of the study, methods, main findings, and conclusions. For article types including Original Article, Brief Report, Review, Policy Forum, and Case Report, a one-paragraph abstract consisting of no more than 250 words must be included in the manuscript. For News and Letters, a brief summary of main content in 150 words or fewer should be included in the manuscript. Abbreviations must be kept to a minimum and non-standard abbreviations explained in brackets at first mention. References should be avoided in the abstract. Key words or phrases that do not occur in the title should be included in the Abstract page.

Introduction: The introduction should be a concise statement of the basis for the study and its scientific context.

Materials and Methods: The description should be brief but with sufficient detail to enable others to reproduce the experiments. Procedures that have been published previously should not be described in detail but appropriate references should simply be cited. Only new and significant modifications of previously published procedures require complete description. Names of products and manufacturers with their locations (city and country) must be given and sources of origin indicated. All clinical investigations must have been conducted in accordance with Declaration of Helsinki principles. All human and animal studies must have been approved by the appropriate institutional review board(s) and a specific declaration of approval must be made within this section.

Results: The description of the experimental results should be succinct but in sufficient detail to allow the experiments to be understood and interpreted by an independent reader. If necessary, subheadings may be used for an orderly presentation. All figures and tables must be referred to in the text.

Discussion: The data should be interpreted concisely without repeating material already presented in the Results section. Speculation is permissible, but it must be well-founded, and discussion of the wider implications of the findings is encouraged. Conclusions derived from the study should be included in this section.

Acknowledgments: All funding sources should be credited in the Acknowledgments section. In addition, people who contributed to the work but who do not meet the criteria for authors should be listed along with their contributions.

References: References should be numbered in the order in which they appear in the text. Citing of unpublished results, personal communications, conference abstracts, and theses in the reference list is not recommended but these sources may be mentioned in the text. In the reference list, cite the names of all authors when there are fifteen or fewer authors; if there are sixteen or more authors, list the first three followed by et al. Names of journals should be abbreviated in the style used in PubMed. Authors are responsible for the accuracy of the references. Examples are given below:

Tables: All tables should be prepared in Microsoft Word or Excel and should be arranged at the end of the manuscript after the References section. Please note that tables should not in image format. All tables should have a concise title and should be numbered consecutively with Arabic numerals. If necessary, additional information should be given below the table.

Figure Legend: The figure legend should be typed on a separate page of the main manuscript and should include a short title and explanation. The legend should be concise but comprehensive and should be understood without referring to the text. Symbols used in figures must be explained.

Figure Preparation: All figures should be clear and cited in numerical order in the text. Figures must fit a one- or two-column format on the journal page: 8.3 cm (3.3 in.) wide for a single column, 17.3 cm (6.8 in.) wide for a double column; maximum height: 24.0 cm (9.5 in.). Please make sure that the symbols and numbers appeared in the figures should be clear. Please make sure that artwork files are in an acceptable format (TIFF or JPEG) at minimum resolution (600 dpi for illustrations, graphs, and annotated artwork, and 300 dpi for micrographs and photographs). Please provide all figures as separate files. Please note that low-resolution images are one of the leading causes of article resubmission and schedule delays. All color figures will be reproduced in full color in the online edition of the journal at no cost to authors.

Units and Symbols: Units and symbols conforming to the International System of Units (SI) should be used for physicochemical quantities. Solidus notation (e.g. mg/kg, mg/mL, mol/mm/min) should be used. Please refer to the SI Guide www.bipm.org/en/si/ for standard units.

Supplemental data: Supplemental data might be useful for supporting and enhancing your scientific research and BioScience Trends accepts the submission of these materials which will be only published online alongside the electronic version of your article. Supplemental files (figures, tables, and other text materials) should be prepared according to the above guidelines, numbered in Arabic numerals (e.g., Figure S1, Figure S2, and Table S1, Table S2) and referred to in the text. All figures and tables should have titles and legends. All figure legends, tables and supplemental text materials should be placed at the end of the paper. Please note all of these supplemental data should be provided at the time of initial submission and note that the editors reserve the right to limit the size and length of Supplemental Data.

5. Submission Checklist

The Submission Checklist will be useful during the final checking of a manuscript prior to sending it to BioScience Trends for review. Please visit Download Centre and download the Submission Checklist file.

6. Online Submission

Manuscripts should be submitted to BioScience Trends online at http://www.biosciencetrends.com. The manuscript file should be smaller than 5 MB in size. If for any reason you are unable to submit a file online, please contact the Editorial Office by e-mail at office@biosciencetrends.com.

7. Accepted Manuscripts

Proofs: Galley proofs in PDF format will be sent to the corresponding author via e-mail. Corrections must be returned to the editor (proof-editing@biosciencetrends.com) within 3 working days.

Offprints: Authors will be provided with electronic offprints of their article. Paper offprints can be ordered at prices quoted on the order form that accompanies the proofs.

Page Charge: Page charges will be levied on all manuscripts accepted for publication in BioScience Trends ($140 per page for black white pages; $340 per page for color pages). Under exceptional circumstances, the author(s) may apply to the editorial office for a waiver of the publication charges at the time of submission.

JOURNAL PUBLISHING AGREEMENT (JPA)

Manuscript No.: 

Title: 

Corresponding Author: 

The International Advancement Center for Medicine & Health Research Co., Ltd. (IACMHR Co., Ltd.) is pleased to accept the above article for publication in BioScience Trends. The International Research and Cooperation Association for Bio & Socio-Sciences Advancement (IRCA-BSSA) reserves all rights to the published article. Your written acceptance of this JOURNAL PUBLISHING AGREEMENT is required before the article can be published. Please read this form carefully and sign it if you agree to its terms. The signed JOURNAL PUBLISHING AGREEMENT should be sent to the BioScience Trends office (Pearl City Koishikawa 603, 2-4-5 Kasuga, Bunkyo-ku, Tokyo 112-0003, Japan; E-mail: office@biosciencetrends.com; Tel: +81-3-5840-8764; Fax: +81-3-5840-8765).

1. Authorship Criteria
As the corresponding author, I certify on behalf of all of the authors that:
1) The article is an original work and does not involve fraud, fabrication, or plagiarism.
2) The article has not been published previously and is not currently under consideration for publication elsewhere. If accepted by BioScience Trends, the article will not be submitted for publication to any other journal.
3) The article contains no libelous or other unlawful statements and does not contain any materials that infringes upon individual privacy or proprietary rights or any statutory copyright.
4) I have obtained written permission from copyright owners for any excerpts from copyrighted works that are included and have credited the sources in my article.
5) All authors have made significant contributions to the study including the conception and design of this work, the analysis of the data, and the writing of the manuscript.
6) All authors have reviewed this manuscript and take responsibility for its content and approve its publication.
7) I have informed all of the authors of the terms of this publishing agreement and I am signing on their behalf as their agent.

2. Copyright Transfer Agreement
I hereby assign and transfer to IACMHR Co., Ltd. all exclusive rights of copyright ownership to the above work in the journal BioScience Trends, including but not limited to the right 1) to publish, republish, derivate, distribute, transmit, sell, and otherwise use the work and other related material worldwide, in whole or in part, in all languages, in electronic, printed, or any other forms of media now known or hereafter developed and the right 2) to authorize or license third parties to do any of the above.

I understand that these exclusive rights will become the property of IACMHR Co., Ltd., from the date the article is accepted for publication in the journal BioScience Trends. I also understand that IACMHR Co., Ltd. as a copyright owner has sole authority to license and permit reproductions of the article.

I understand that except for copyright, other proprietary rights related to the Work (e.g. patent or other rights to any process or procedure) shall be retained by the authors. To reproduce any text, figures, tables, or illustrations from this Work in future works of their own, the authors must obtain written permission from IACMHR Co., Ltd.; such permission cannot be unreasonably withheld by IACMHR Co., Ltd.

3. Conflict of Interest Disclosure
I confirm that all funding sources supporting the work and all institutions or people who contributed to the work but who do not meet the criteria for authors are acknowledged. I also confirm that all commercial affiliations, stock ownership, equity interests, or patent-licensing arrangements that could be considered to pose a financial conflict of interest in connection with the article have been disclosed.
