BioScience Trends is one of a series of peer-reviewed journals of the International Research and Cooperation Association for Bio & Socio-Sciences Advancement (IRCA-BSSA) Group and is published bimonthly by the International Advancement Center for Medicine & Health Research Co., Ltd. (IACMHR Co., Ltd.) and supported by the IRCA-BSSA and Shandong University China-Japan Cooperation Center for Drug Discovery & Screening (SDU-DDSC).

BioScience Trends devotes to publishing the latest and most exciting advances in scientific research. Articles cover fields of life science such as biochemistry, molecular biology, clinical research, public health, medical care system, and social science in order to encourage cooperation and exchange among scientists and clinical researchers.

BioScience Trends publishes Original Articles, Brief Reports, Reviews, Policy Forum articles, Case Reports, News, and Letters on all aspects of the field of life science. All contributions should seek to promote international collaboration.

Summary

Diminished ovarian reserve (DOR) has a high morbidity rate worldwide and has become a primary cause of infertility. DOR is a daunting obstacle in in vitro fertilization (IVF) and leads to poor ovarian response, high cancellation rates, poor IVF outcomes, and low pregnancy rates. Abnormal autoimmune function may also contribute to DOR. Dehydroepiandrosterone (DHEA) is a C19 androgenic steroid. DHEA is secreted mainly by the adrenal gland, and its secretion declines with age. DHEA has a pro-inflammatory immune function that opposes cortisol. The cortisol to DHEA ratio increases with age, which may lead to decreased immune function. DHEA supplementation helps improve this situation. A number of clinical case control studies and several prospective randomized clinical trials have observed a positive effect of DHEA supplementation in women with DOR. However, the underlying mechanism by which DHEA improves ovarian reserve remains unclear. DHEA functions as an immune regulator in many different tissues in mammals and may also play an important role in regulating the immune response in the ovaries. The conversion of DHEA to downstream sex steroids may allow it to regulate the immune response there. DHEA can also enhance the Th1 immune response and regulate the balance of the Th1/Th2 response. DHEA treatment can increase selective T lymphocyte infiltration in mice, resulting in a decline in the CD4⁺ T lymphocyte population and an upregulation of the CD8⁺ T lymphocyte population in ovarian tissue, thus regulating the balance of CD4⁺/CD8⁺ T cells. This review mainly focuses on how DHEA supplementation affects regulation of the immune response in the ovaries.

**Keywords:** Dehydroepiandrosterone (DHEA), diminished ovarian reserve (DOR), immune response, cytokine, lymphocytes, endocrino-immune network

1. Introduction

Ovarian reserve decreases within a certain range as women age. Women with a lower ovarian reserve outside of this range are identified as having diminished ovarian reserve (DOR). Reduced ovarian reserve consists of a decline in the number of primordial follicles, a decrease in the size of the dynamic reserve of small antral follicles, and a deterioration in oocyte quality. These changes are evident as women age. Some genetic mutations and disorders of the endocrine system can accelerate or modulate the rate at which the ovarian reserve is exhausted and cause premature ovarian insufficiency (POI) (1). Among the various causes of DOR, abnormal immune function may be a great contributor to this phenomenon (2). Patients with DOR often become infertile and have a poor response to in vitro fertilization (IVF) (3,4). Researchers have developed different protocols to solve this problem, but none of them has proven to be ideal for such patients (5-7). Dehydroepiandrosterone (DHEA) is a C19 androgenic steroid that has been found to be effective in many areas. Decades of observational
studies both in clinical settings and in animals have found that the levels of DHEA(S) are inversely associated with cardiovascular risk, morbidity, and mortality (8). In ovariectomized rabbits, DHEA was found to protect against atherosclerosis because it alleviated inflammation in endothelial cells (9). DHEA is able to cross the brain-blood barrier. DHEA also has neuroactive characteristics and it has positive effects on human mood, emotions, and behaviors (10,11). In 2000, Casson et al. were the first to use DHEA supplementation in women with DOR to improve the response to ovarian stimulation (12). Many researchers have devoted their attention to the effects of DHEA supplementation in women with DOR. Narkwichean et al. conducted a meta-analysis that showed that DHEA administration resulted in a significant increase in the number of oocytes retrieved in women with DOR according to some clinical trials. However, more clinical trials must be performed to verify the results (13). In ovariectomized sheep, DHEA supplementation was effective at in vivo ovarian folliculogenesis (14). Similar results have been observed in Wistar rats in an in vivo model (15). However, the underlying mechanism by which DHEA improves ovarian reserve remains unclear. DHEA can regulate immune cell function (16), and it may regulate the function of many different types of tissue in mammals. Utilizing a human subcutaneous preadipocyte cell line, Chub-S7, McNeils et al. found that DHEA inhibition of the amplification of glucoorticoid action was mediated by 11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) (17). Lazaridis et al. performed an in vitro study that showed that DHEA also served as a neurosteroid, directly interacting with nerve growth factor (NGF) to prevent neuronal apoptosis (18). In ovariectomized rats, DHEA showed the potential to correct oxidative stress-induced endothelial dysfunction (19). Thus, DHEA may play an important role in regulating the immune response in the ovaries. DHEA treatment may also modulate the lymphocyte response in both human and animal trials (20,21). The current review mainly focuses on how DHEA supplementation affects regulation of the immune response in the ovaries.

2. DHEA supplementation has proven effective in women

DHEA (5-androsten-3β-ol-17-one) is a C19 androgenic steroid (Figure 1) that is secreted primarily by the adrenal zona reticularis. DHEA is synthesized by the steroidogenic enzyme P450c17 and partly by the ovary (22). The secretion of DHEA has a diurnal rhythm similar to that of cortisol (23,24). In humans, the intra-individual concentrations of DHEA and its sulphate, DHEAS, steadily decline with advancing age, unlike those of other androgenic steroids. The concentration peaks during the third decade of life, with a clear sex difference since adult women have lower concentrations of DHEA than men (25-27). Given this characteristic of age-related decline, DHEA supplementation may help to improve age-related damage in human beings. To date, no studies have noted an apparent effect of DHEA in healthy males (28). Some double-blind placebo-controlled trials have demonstrated that DHEA does not markedly improve well-being or cognitive function in healthy elderly men and women over age 50 (28,29). However, DHEA was found to modulate immune function in postmenopausal women (30). DHEA is also reported to affect cardiovascular and immunological function differently in women and men (31).

2.1. The effects of DHEA supplementation in women with DOR

There are no set criteria for DOR thus far, but women with DOR share a poor ovarian response to stimulation as well as high cancellation rates and low pregnancy rates. A poor ovarian response in a previous IVF-embryo transfer (ET) cycle means that fewer oocytes were retrieved or that these oocytes were less mature follicles after high-dose gonadotropin stimulation. Different researchers have defined this process differently. Many studies have investigated the effects of DHEA supplementation on ovarian function. Twelve of those studies were analyzed in the current study (see Table 1). DHEA supplementation is usually oral and administered at 25 mg, three times a day, or 75-90 mg for the entire day, for 6 to 24 weeks. A previous case-control study showed that DHEA improved ovarian reserve and that it significantly increased antral follicle counts (AFCs), anti-Müllerian hormone (AMH) levels (32-34), numbers of fertilized oocytes, normal day 3 embryos, embryos transferred, and the average embryo score per oocyte (35) while significantly decreasing day 3 follicle-stimulating hormone (FSH) (33), fertilized aneuploid embryos (36), and miscarriage rates (37) (all p-values < 0.05). Estradiol (E2) levels tripled according to two studies (12,38) but decreased according to a third (34). Several randomized prospective controlled studies investigated the effects of DHEA supplementation but their results were inconsistent. Some researchers obtained the same results as described earlier (34,38-40), but the number of oocytes retrieved and the fertilization rate remained inconsistent (38,40,41), whereas others failed to show that DHEA was effective at improving IVF outcomes (40,41). These studies,
Abbreviations: ↑, increased; ↓, decreased; DHEA, dehydroepiandrosterone; DOR, diminished ovarian reserve; FSH, follicle stimulating hormone; IUI, intrauterine insemination; IVF, in vitro fertilization; IVF-ET, in vitro fertilization-embryo transfer; AFC, antral follicle count; POI, premature ovarian insufficiency; IVF-ICSI, in vitro fertilization-intracytoplasmic sperm injection; BMP-15, bone morphogenetic protein-15.

however, cannot be compared statistically since there were no set criteria to define DOR. Usually, DOR was defined as abnormally elevated age-specific baseline FSH levels and/or abnormally low AMH levels (42-44)), elevated inhibin-B levels, and AFCs less than 4 to 5 (33,34,38,41).

2.2. Immune function of DHEA

Use of DHEA has been described in many areas and is mainly considered because of its immunoregulatory function. DHEA has an effect on human neuroendocrine cells and plays an important role in immune regulation, especially by balancing pro-inflammatory and anti-inflammatory signals. Humans develop inflammation with age, which involves the up-regulation of certain pro-inflammatory cytokines, such as interleukin (IL)-1, IL-6, tumor necrosis factor (TNF)-α, IL-12, interferon (IFN)-α, and IFN-β. In old age, these cytokines negatively impact various systems in the body (45-47). This leads to an unbalanced relationship between pro-inflammatory cytokines and anti-inflammatory cytokines (IL-4, IL-6, IL-13, IL-10) (48). DHEA is part of the hypothalamus-pituitary-adrenal (HPA) axis. When the HPA axis is activated, both cortisol and DHEA are released. Cortisol has an anti-inflammatory effect, whereas DHEA appears to have an opposing effect. As DHEA levels decline with age, the molar ratio of cortisol to DHEAs increases and may interact with weakened immune function (49,50). Elderly bereaved participants showed decreased production of neutrophil reactive oxygen species and an increased cortisol to DHEAS ratio (10). DHEA supplementation has a positive effect on immunity in the elderly. Treatment with 20 mg/kg DHEA for 8 weeks reversed antioxidant parameters, such as decreased superoxide dismutase activity in the brain and heart, decreased inducible nitric oxide synthase mRNA levels, and increased heme oxygenase mRNA levels, in aged rats (51). Buoso et al. found that cortisol acted in a dose-related manner in vitro and in vivo on human guanine nucleotide binding protein and the beta polypeptide 2 like 1 (GNB2 L1) promoter repressor, which reduced receptor for Activated C Kinase 1 (RACK-1) mRNA and protein expression. Prolonged DHEA exposure counteracted the effects of cortisol and restored RACK-1 levels and cytokine production (assessed with lipopolysaccharide (LPS)-induced TNF-α release); this most likely occurred as a result of interfering with glucocorticoid receptor binding to the glucocorticoid responsive element (GRE) sequence (52). Furthermore, DHEA supplementation has been proven to be effective in treating other diseases and improving organ function and survival. However, these mechanisms are not yet fully understood. Over the past few years, an increasing number of researchers have turned their attention to the effects of DHEA on regulation of the immune response, but these effects have been produced in non-human mammals. In aged baboons, researchers found increased serum C-reactive protein and increased cytokine release from unstimulated peripheral blood mononuclear cells. Supplementary DHEA improved outcomes in a murine polymicrobial sepsis and trauma model by restoring TNF-α in the liver and lungs after 48 hours and attenuating it in the liver after 96 hours, much like a time- and organ-dependent modulator (53). DHEA supplementation also leads to a restoration of splenocyte proliferation, a decrease in the rate of cellular apoptosis of splenocytes, and an attenuation of increased IL-6 levels (54). DHEA also restored peripheral blood mononuclear cell (PBMC) function and increased the ability of human PBMCs patients with depressed immune function to release pro-inflammatory cytokines (IL-1β, IL-6, and TNF-α) following major abdominal surgery (55).

3. DHEA and the immune response in the ovaries

The level of the immune response in the ovaries changes with age along with the ovarian reserve. There is substantial interaction between the immune system and the ovaries as immune cells are associated with regulation at every level of the hypothalamus-pituitary-ovarian axis by regulating growth and regression of both follicles and the corpus luteum (56-58). In adult ovaries, activated myeloid dendritic cells (MDC) also play a role in follicular development and atresia, as well as differentiation of the corpus luteum. MDC and T cells massively infiltrate the corpus luteum, resulting in parenchymal and vascular regression, which then leads to the demise of the corpus luteum (59). DHEA improves the ovarian reserve of women with age-related DOR women with POI even though POI is more closely related to ovarian immune disorders. Young women who have a history or family history of autoimmunity are at risk for POI (60,61). There are many types of autoimmune abnormalities (Table 2). There are three different types of autoimmune ovarian insufficiency: autoimmune ovarian insufficiency associated with adrenal autoimmunity, autoimmune

ovarian insufficiency associated with non-adrenal autoimmunity, and isolated idiopathic POI (iPOI) (62); adrenal autoimmunity is the most prevalent (2,63). Researchers tested for triple CGG repeats on both alleles of the fragile X mental retardation 1 (FMR1) gene and assessed autoimmune status (including an antiphospholipid antibody panel, an antinuclear antibody panel, total immunoglobulin levels, thyroid antibodies, and antiadrenal antibodies), and then they found that abnormal autoimmune function, including expansions in triple CGG repeats on the FMR1 gene, increased the risk for POI (64,65).

Although the effects of DHEA supplementation in women with DOR are readily evident, the mechanism behind these effects remains unclear. Given the complex immune function of DHEA and ovarian immune disorders in women with DOR, some researchers have begun to explore the immune function of DHEA in women with DOR. However, the research reports to date on this topic are extremely limited. Only a few studies have been conducted and their results are summarized below.

3.1. Conversion to other steroids

No certain specific receptor for DHEA has been found to date, and some theories suggest that DHEA may function once steroidogenic enzymes convert it to other downstream steroids, especially sex steroids such as estrone and androgens (Figure 2). Small structural changes in androgens result in markedly different biological effects. Steroidogenic enzymes have tissue-specific patterns of expression; thus, DHEA may have a special function. These steroids interact critically with immune function. Estrone can shift the female immune system to a Th2-type response in the luteal phase, whereas postmenopausal women often exhibit enhanced Th1 cytokines (66). As mentioned previously, DHEA can restore PBMC function and increase the ability of human PBMCs to release pro-inflammatory cytokines after surgery via the estrogen receptor; this immunomodulatory effect of DHEA appears to be connected to estrogen receptors (55). Although total androgen concentrations were not associated with pregnancy during DHEA supplementation in women with POI, interaction between DHEA and total and free testosterone also significantly affected pregnancy rates at the start of an IVF cycle (67). Total testosterone is significantly lower in women with POI or abnormal FMR1 genotypes (68). The efficiency of androgen conversion from DHEA to testosterone and the amplitude of testosterone gain are related to pregnancy rates. Conversion is usually more pronounced in young women and women with selected FMR1 genotypes/subgenotypes (69). DHEA and testosterone also suppressed canavalin A (Con A)-induced proliferation of thymocytes in vitro, and DHEA is less potent than testosterone, which means that the balance between the two steroids can alter immune homeostasis (70). Testosterone and estradiol levels vary widely after DHEA administration, and the testosterone to estradiol ratio increased significantly in seven healthy nonobese postmenopausal women (71).

When steroidogenic enzymes convert DHEA to other steroids, those enzymes have a substantial effect on the immune response. Although women with POI have a poor ovarian follicle pool compared to healthy fertile women, women with POI and steroidogenic cell autoimmunity (SCA-POI), which involves circulating autoantibodies directed against steroidogenic enzymes such as 21-α-hydroxylase, 17-β-hydroxylase, and side-chain cleavage enzyme (P450sccAb) (72-76), have a better ovarian reserve than women with iPOI and postmenopausal women. Steroid sulphatase is controlled by an x-linked gene. Women have twice the amount of steroid sulphatase in macrophages. The
macrophages enter peripheral lymphoid organs through afferent lymphatic drainage (77,78). IL-4, which is a typical Th2 cytokine, increases the expression of 3-beta-hydroxysteroid dehydrogenase type 2 (HSD3B2) mRNA, and thus may lead to the increased production of estrogen from DHEA (79).

3.2. Balance of the Th1 and Th2 immune response

Cytokines have an extremely important place in the immune response. They can influence communication between T cells, macrophages, and other immune cells. Numerous studies in mice and humans have deduced the presence of T helper (Th) cells based on the profile of cytokine secretion. The Th1-type immune response is thought to be associated with IgG2a production, which is driven by cytokines such as IFN-γ, IL-2, TNF-α, and IL-12, whereas the Th2-type immune response involves IgE production driven by specific cytokines (IL-4, IL-5, IL-10, and IL-13) (80,81).

DHEA restores the cell-mediated immune response of pro-inflammatory cytokines (IL-1, IL-6, TNF-α, and IL-18). Mice treated with DHEA exhibited increased production of cytokines such as serum TNF-α, IL-6, IL-12p70, and IFN-γ (82,83). DHEA supplementation also increases vascular cell adhesion molecule 1 (VCAM-1) and intercellular cell adhesion molecule 1 (ICAM-1) in the granulosa cell layer of cysts and the theca cell layer of all follicles and cysts when DHEA androgenization induces the formation of cysts (83). DHEA may improve ovarian function in women with poor ovarian response by activating anti-apoptotic processes in cumulus cells. These processes most likely involve the upregulation of genes related to extracellular matrix (ECM) formation and downregulating genes related to cell development, differentiation, and apoptosis (84). In other areas, DHEA supplementation has been reported to have an effect on regulation of the Th1/Th2 response. In ovalbumin-sensitized asthmatic female mice, Th2-associated cytokines and chemokines were inhibited after DHEA administration, which led to hyper-responsiveness (85). DHEA decreased the release of anti-inflammatory cytokines (IL-2 and IL-10, which are also Th2-associated cytokines) and it reduced the expression of the activation marker CD69 on CD4+ T cells (20). All of these effects may bring about an enhanced Th1 response and a weakened Th2 response and lead to a new balance in the Th1/Th2 response.

3.3. Balance between CD4+/CD8+ T cells

DHEA also improves immune function by regulating the proliferation of and balance between different types of lymphocytes. During the culturing of T lymphocytes from BALB/c mice in vitro, DHEA did not change the viability of T lymphocytes, but it did increase oxidative stress by reducing antioxidant molecules, such as glutathione (GSH) (86). Burdick et al. conducted a study and found that oral administration of DHEAs in young pigs increased in vitro lymphocyte proliferation following immunization and that it increased the in vivo response of immunization against keyhole limpet haemocyanin (KLH), thus increasing the neutrophil to lymphocyte ratio and increasing the concentration of IgG (21). DHEA effects opposite those of cortisol; thus, the cortisol to DHEA ratio may influence the differentiation of T cells. Extra-thymic (DP) CD4+/CD8+ T cells positively correlated with circulating levels of TNF-α and with the cortisol/DHEAs ratio (87). Flow cytometry showed that DHEA treatment in mice significantly increased the CD4+ lymphocyte population and decreased the CD8+ lymphocyte population, thus modulating the CD4+/CD8+ lymphocyte balance in both ovarian tissue and retroperitoneal lymph nodes (82). This may be due to the selective T lymphocyte infiltration of ovarian tissue (88).

4. Conclusion

DHEA attenuates diminished ovarian reserve and helps to obtain better results in IVF cycles. DHEA may modulate ovarian immunity through its conversion to other downstream steroids, by balancing the Th1/Th2 immune response, or by modulating the types and behavior of T lymphocytes. The mechanism underlying the immune effects of DHEA on ovarian tissue needs to be studied further.

Polyphosphate-induced matrix metalloproteinase-3-mediated differentiation in rat dental pulp fibroblast-like cells

Taiki Hiyama, Nobuaki Ozeki*, Naoko Hase, Hideyuki Yamaguchi, Rie Kawai, Ayami Kondo, Makio Mogi, Kazuhiko Nakata

1. Introduction

Inorganic polyphosphate [Poly(P)] is a linear polymer consisting of tens to hundreds of orthophosphate residues linked by high-energy phosphoanhydride bonds. In mammals, Poly(P) is found in erythrocytes and cells of the brain, heart, lung, and liver (1-4). The most researched and well-known role of Poly(P) is in the promotion of intracellular calcification (5). Because Poly(P) induces alkaline phosphate (ALP) activity and up-regulates osteopontin (OP) and osteocalcin (OC) gene expression (6), Poly(P) is thought to play an important role in the maturation of bone-related immature cells, and may be involved in the construction of bone tissue by osteoblasts.

In addition to blood vessels and nerves, fibroblasts are a significant component of dental pulp tissue (7) and thus might represent a novel therapeutic target for treating pulpitis. However, the effect of Poly(P) regulation of differentiation on dental pulp fibroblast-like cells (DPFCs) has not been well defined.

Matrix metalloproteinase (MMP)-3 and interstitial collagenase (MMP-1) are produced by fibroblasts in response to increased levels of inflammatory cytokines in dental pulp injury and diseases such as periodontitis and rheumatoid arthritis (8,9). MMP-3 has been implicated in the joint and soft-tissue destruction associated with these conditions, where it participates in the inflammatory response (10-14). MMP-3 synthesis is tightly controlled in vivo (13,15). Our previous study reported that proinflammatory cytokine-induced MMP-3 actually accelerates wound healing following dental pulp injury (16-18) and promotes cell proliferation (17,19,20).

Recently, roles of Poly(P) have been suggested in apoptosis and modulation of the mineralization process in bone tissue (21,22). We previously reported that Poly(P) induces MMP-3-mediated proliferation of odontoblast-like cells derived from induced pluripotent stem cells (23). Although we previously reported that

---

Summary

Inorganic polyphosphate [Poly(P)] induces differentiation of osteoblastic cells. In this study, matrix metalloproteinase (MMP)-3 small interfering RNA (siRNA) was transfected into purified rat dental pulp fibroblast-like cells (DPFCs) to investigate whether MMP-3 activity induced by Poly(P) is associated with cell differentiation into osteogenic cells. Real-time quantitative polymerase chain reaction, western blotting, and an MMP-3 activity assay were used in this study. Poly(P) enhanced expression of mature odontoblast markers dentin sialophosphoprotein (DSPP) and dentin matrix protein (DMP)-1 in DPFCs. These cells also developed an osteogenic phenotype with increased expression of osteocalcin (OC) and osteopontin (OP), high alkaline phosphatase (ALP) activity, and an increased calcification capacity. Poly(P) induced the expression of MMP-3 mRNA and protein, and increased MMP-3 activity. MMP-3 siRNA potently suppressed the expression of osteogenic biomarkers ALP, OC, OP, DSPP, and DMP-1, and blocked osteogenic calcification. Taken together, Poly(P)-induced MMP-3 regulates differentiation of osteogenic cells from DPFCs.

Keywords: Dental pulp, osteogenic cells, dentin sialophosphoprotein, dentin matrix protein-1

1. Introduction

Inorganic polyphosphate [Poly(P)] is a linear polymer consisting of tens to hundreds of orthophosphate residues linked by high-energy phosphoanhydride bonds. In mammals, Poly(P) is found in erythrocytes and cells of the brain, heart, lung, and liver (1-4). The most researched and well-known role of Poly(P) is in the promotion of intracellular calcification (5). Because Poly(P) induces alkaline phosphate (ALP) activity and up-regulates osteopontin (OP) and osteocalcin (OC) gene expression (6), Poly(P) is thought to play an important role in the maturation of bone-related immature cells, and may be involved in the construction of bone tissue by osteoblasts.

In addition to blood vessels and nerves, fibroblasts are a significant component of dental pulp tissue (7) and thus might represent a novel therapeutic target for treating pulpitis. However, the effect of Poly(P) regulation of differentiation on dental pulp fibroblast-like cells (DPFCs) has not been well defined.

Matrix metalloproteinase (MMP)-3 and interstitial collagenase (MMP-1) are produced by fibroblasts in response to increased levels of inflammatory cytokines in dental pulp injury and diseases such as periodontitis and rheumatoid arthritis (8,9). MMP-3 has been implicated in the joint and soft-tissue destruction associated with these conditions, where it participates in the inflammatory response (10-14). MMP-3 synthesis is tightly controlled in vivo (13,15). Our previous study reported that proinflammatory cytokine-induced MMP-3 actually accelerates wound healing following dental pulp injury (16-18) and promotes cell proliferation (17,19,20).

Recently, roles of Poly(P) have been suggested in apoptosis and modulation of the mineralization process in bone tissue (21,22). We previously reported that Poly(P) induces MMP-3-mediated proliferation of odontoblast-like cells derived from induced pluripotent stem cells (23). Although we previously reported that
Poly(P)-induced MMP-3-mediated proliferation of rat DPFCs is mediated by a Wnt5 signaling cascade (24), it is unknown whether Poly(P) is associated with differentiation. Therefore, we investigated the physiological effect of Poly(P) on DPFC differentiation in vitro. We reveal a novel role of Poly(P) in the regulation of MMP-3 activity during the differentiation of osteogenic cells from DPFCs.

2. Materials and Methods

2.1. Materials

Type-65 Poly(P) with an average chain length of 65 phosphate residues was prepared from sodium tripolyphosphate (Taihei Chemical Industrial Co., Ltd., Osaka, Japan). Concentrations of Poly(P) are shown in terms of phosphate residues (25). As a control, sodium phosphate buffer (pH 6.9) was used instead of Poly(P).

2.2. Cell culture

The study protocol (No. 63) was reviewed and approved by the Animal Experimentation Committee, School of Dentistry, Aichi Gakuin University, Japan. DPFCs were isolated from rat incisors and cultured using a previously described protocol (20). The proportion of platelet-derived growth factor receptor (PDGFR)-α positive cells in the total fibroblast-like cell population is a measure of purity of DPFCs (24). Therefore, using flow cytometry, we evaluated the ratio of PDGFR-α-positive cells as a percentage of the total differentiated cells to determine the purity of the differentiated cell population. Our DPFC cultures showed 98.64 ± 5.2% homogeneity (% total, n = 3). In all experiments, DPFCs were used at passages 2-5. Cells were seeded into six-well tissue culture plates at a density of 1 × 10⁵ cells/cm². To expose the cells to Poly(P), the culture medium was replaced with alpha-minimal essential medium containing 10% fetal bovine serum and Poly(P), followed by 7 days of culture.

2.3. Functional assay for assessment of the osteogenic phenotype

To assess the phenotype of the cultured cells, we measured ALP activity and calcification (as a marker of differentiation). ALP activity was determined using an ALP Staining Kit (Primary Cell Co., Ltd., Hokkaido, Japan). Mineralization from the Poly(P)-treated cells was quantified using an Alizarin red S (ARS) assay (Sigma-Aldrich, St. Louis, MO, USA). ARS staining was quantified using a previously reported method (26) and photographed using a BZ-9000 microscope (Keyence, Osaka, Japan) and/or an IN Cell Analyzer 2000 (GE Healthcare UK Ltd, Buckinghamshire, England).

2.4. Real-time quantitative polymerase chain reaction (qRT-PCR) analysis

qRT-PCR was performed for all samples and standards in triplicate with approximately 25 ng RNA, 0.25 mL Quantitect RT Mix (Qiagen Inc., Valencia, CA, USA), and 1.25 mL of 20× Primer/Probe Mix (rat ALP [ALPL]: Rn00575319_g1; rat OC [BGLAP]: Rn00566386_g1; rat OP [SPP1]: Rn01449972_m1; rat DSPP [DSPP]: Rn02132391_s1; rat DMP-1 [DMP-1]: Rn01450120_m1; rat MMP-3: Rn00591740_m1; human MMP-1 (rat available): Hs00899658_m1; rat MMP-2: Rn01538170_m1; rat MMP-9: Rn00579162_m1; rat MMP-13: Rn01448194_m1). The standard curve method was used to determine the relative quantification of gene expression with glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and 18S rRNA as controls. Analysis was performed by the delta-delta Ct method.

2.5. Western blot analysis

Cells were cultured for 6 h with or without Poly(P) and then lysed using cell lysis buffer (Cell Signaling Technology Japan, K.K., Tokyo, Japan). Protein lysates were separated on SDS-polyacrylamide gels (12%) in preparation for western blot analysis using anti-ALP, -OC, -OP, -MMP-3, -DMP-1, and β-tubulin polyclonal antibodies (sc-271431, sc-30044, sc-10593, sc-6839, sc-5538, sc-13595, sc-6840, sc-30073, and sc-9935, respectively; Santa Cruz Biotechnology, Inc., Santa Cruz, CA, USA). Visualization of blotted protein bands was performed using a Multi Gauge-Ver3.X (Fujifilm, Tokyo, Japan).

2.6. Measurement of MMP-3 activity

The protocol for measurement of MMP-3 activity has been described previously (27,28) and is now a commercially available MMP-3 activity assay kit (SensoLyte™ 520 MMP-3 assay kit; AnaSpec, San Jose, CA, USA). Silencing of the MMP-3 gene by small interfering RNA (siRNA) transfection

Commerically available MMP-3 siRNA (sc-61874, Santa Cruz Biotechnology, Inc.) was transfected into cultured cells using an siRNA reagent system (sc-45064, Santa Cruz Biotechnology, Inc.) according to the manufacturer's protocol. GAPDH siRNA and a control siRNA without known homology to any vertebrate sequence (Thermo Scientific, Lafayette, CO, USA) were used as positive and negative controls, respectively.

2.7. Silencing of the MMP-3 gene by small interfering RNA (siRNA) transfection

Commercially available MMP-3 siRNA (sc-61874, Santa Cruz Biotechnology, Inc.) was transfected into cultured cells using an siRNA reagent system (sc-45064, Santa Cruz Biotechnology, Inc.) according to the manufacturer's protocol. GAPDH siRNA and a control siRNA without known homology to any vertebrate sequence (Thermo Scientific, Lafayette, CO, USA) were used as positive and negative controls, respectively.

2.8. Statistical analysis

Data presented in bar graphs are the means ± standard
The majority of Poly(P)-treated DPFCs showed strong ALP expression, whereas control cells had undetectable ALP expression (Figure 1B-b). Extensive deposits of calcified matrix were observed in Poly(P)-treated DPFC cultures, whereas calcified matrix was not apparent in control cell cultures (Figure 1C-b). Consistently, Poly(P) treatment induced a marked increase in ARS signals (Figure 1C-a, b). Taken together, Poly(P) induced osteogenic cells from DPFCs.

3.2. Poly(P) induces expression of MMP-3 mRNA and MMP-3 activity in DPFCs

MMP-3 induction by 0.1 mM Poly(P) was assessed using qRT-PCR to measure changes in MMP-3 mRNA expression. The levels of MMP-3 mRNA expression in Poly(P)-treated cells were significantly increased \((p < 0.05)\) at days 3, 5, and 7 of culture (Figure 2A). Furthermore, MMP-3 activity was significantly increased \((p < 0.01)\) at days 3, 5, and 7 following treatment of DPFCs with Poly(P) for 24 h (Figure 2C).
Bone-associated cells also express other MMP proteins including MMP-1, MMP-2, MMP-9, and MMP-13 (29-31). However, we found no significant changes in their expression levels in DPFCs treated with 0.1 mM Poly(P) (Figure 2B).

MMP-3 activity is precisely regulated at the post-translational level as a precursor zymogen and by endogenous tissue inhibitors of metalloproteinases (TIMPs) (32). Although TIMP-2 and TIMP-3 are known to be induced by cytokines (32), we found that TIMP-1, TIMP-2, and TIMP-3 proteins were constitutively expressed in all experimental conditions (data not shown).

3.3. siRNA silencing of MMP-3 blocks osteogenic differentiation

To examine whether the up-regulation of MMP-3 expression was associated with osteogenic differentiation, DPFCs were transfected with MMP-3 siRNA or a control scrambled siRNA, and then treated with Poly(P) as described above. Transfection of MMP-3 siRNA abrogated the induction of osteogenic differentiation markers ALPL, BGLAP, SPP1, DSPP, and DMP-1 (p < 0.05, Figure 3A). Similar changes in the protein levels of each marker were observed in western blot analyses (Figure 3B). Furthermore, MMP-3 siRNA blocked...
induction of ALP activity in Poly(P)-treated cells ($p < 0.01$, Figure 4A-a, b). Similarly, the induction of calcification was markedly suppressed ($p < 0.05$) by Poly(P) treatment of MMP-3-depleted cells (Figure 4B-a, b). Collectively, these data show that expression of MMP-3 is required for osteogenic-specific functions in DPFCs.

4. Discussion

This study indicated that Poly(P)-treated DPFCs can be a novel in vitro model of dental pulp regeneration. Poly(P) at a concentration of 0.1 mM induced MMP-3 expression in DPFCs (Figure 2A) and led to enhanced DPFC differentiation into osteogenic cells (Figure 1A–C), although we were unable to precisely determine how many DPFCs had differentiated. However, phenotypic characterization based on calcification and the levels of ALPL (ALP), BGLAP (OC), SPP1 (OP), DSPP, and DMP-1 suggested that a large proportion of the DPFC population differentiated into osteogenic cells (Figure 1A-a, b).

We have previously demonstrated that the inflammatory cytokine interleukin-1β or a cytokine mixture induces MMP-3-regulated cell proliferation and suppresses apoptosis in rat DPFCs (19,20). Moreover, we previously reported that Poly(P)-induced, MMP-3-mediated proliferation in rat DPFCs is mediated by a Wnt5 signaling cascade (24). Because we had no definite data on Poly(P)-induced MMP-3 in terms of IGF-1/Pi3K/Akt and MAPK signaling pathways (33,34) in osteogenic differentiation, it remains to be shown. This study is the first report of Poly(P)-induced, MMP-3-mediated responses in the differentiation of DPFCs. Considering the effect of MMP-3 on osteogenic cell differentiation, the present findings suggest that targeting the MMP-3 gene in these osteogenic cells may have a utility in the treatment of suppurative pulpitis. Additionally, Poly(P)-treated DPFCs could serve as an effective model to explore the pathophysiological mechanisms of wound healing. Furthermore, our current evidence suggests that Poly(P)-induced MMP-3 has previously unrecognized physiological functions in wound healing and dental pulp tissue regeneration.

We showed that Poly(P)-induced cells acquired osteogenic-specific functions following differentiation from DPFCs. Poly(P)-treated DPFCs appeared to be predominantly odontoblasts and osteoblasts. A major concern is that we were unable to identify the differentiated cells as odontoblasts because these cells also expressed specific osteoblastic markers including OC and OP. We speculate that DPFCs contain a small population of dental pulp stem cells. Therefore,
ostegenic cells may be predominantly derived from dental pulp stem cells, which remains to be elucidated.

The findings presented here support our previous reports (19,20) and indicate that MMP-3 may have a previously unrecognized physiological function in wound healing and tissue regeneration. Because Poly(P) induces MMP-3-regulated DPFC differentiation into osteogenic cells, the use of Poly(P) represents a potentially superior therapeutic approach for treatment of dental pulp injury instead of applying pulp-capping materials.

Lipopolysaccharide-induced serotonin transporter up-regulation involves PKG-I and p38MAPK activation partially through A3 adenosine receptor

Rui Zhao¹, Shoubao Wang¹, Zhonglin Huang², Li Zhang¹, Xiuying Yang¹, Xiaoyu Bai¹, Dan Zhou¹, Zhizhen Qin¹, Guanhua Du¹,*

Summary
Serotonin transporter (SERT) is a critical determinant of synaptic serotonin (5-hydroxytryptamine, 5-HT) inactivation which plays a critical role in the pathology of depression and other mood disorders. Lipopolysaccharide (LPS), a potent activator of the inflammatory system, has been reported to cause depression symptoms by the modulation of SERT in vivo and in vitro. This study is aimed to investigate the underlying mechanism of LPS-induced SERT modulation. The 4-(4-(dimethylamino) styryl)-N-methylpyridinium iodide (ASP) assay was used to detect dynamic 5-HT uptake as read out of SERT activities in RBL-2H3 cells, and cytosol Ca²⁺ concentrations ([Ca²⁺]i) and nitric oxide (NO) were examined. Using specific cyclic GMP-dependent protein kinase type I (PKG-I), p38 mitogen-activated protein kinases (p38MAPK) and A3 adenosine receptor (A3AR) inhibitors, SERT expression was evaluated by western blot and immunofluorescence analysis. Results showed that 24 h treatment with LPS stimulated 5-HT transport and up-regulate plasma membrane distribution of SERT in RBL-2H3 cells. LPS treatment increased NO and [Ca²⁺]i, and led to significant increases in levels of phosphorylated calcium/calmodulin-dependent protein kinase type II (CaMK-II), inducible NOS (iNOS) and PKG-I as well as active p38 MAPK. Moreover, PKG-I inhibitor KT5823 or p38MAPK inhibitor SB203580 respectively impaired SERT activation and transposition to plasma membrane by LPS. Notably, A3 adenosine receptor inhibitor MRS1191 also hindered SERT stimulation by LPS. In conclusion, LPS-induced 5-HT uptake and transposition to plasma membrane of SERT in RBL-2H3 cells involves CaMK-II/iNOS/PKG-I and p38 MAPK activation, which may be partially mediated by A3 adenosine receptor activation. This finding provides a novel insight into the interrelationship between LPS and depression.

Keywords: Serotonin transport (SERT), lipopolysaccharide, cyclic GMP-dependent protein kinase type I (PKG-I), p38 mitogen-activated protein kinases (p38MAPK), A3 adenosine receptor
SERT function that may underlie the eventual clinical improvement after prolonged exposure to antidepressant drugs (4). Although the entire mechanism responsible has not been elucidated, SERT is subject to multiple postranslational regulations that can rapidly alter 5-HT uptake and clearance rates. Specific cell surface receptors as well as pathways activating protein kinase C (PKC), protein kinase G (PKG) and p38 mitogen activated protein kinase (p38MAPK) regulating SERT trafficking and catalytic function are now well established and received greater attention (5). Zhu et al. revealed two PKG-dependent pathways supporting rapid SERT regulation by A3 adenosine receptor (A3AR), one leading to enhanced SERT surface trafficking, and a separate, p38 MAPK-dependent process augmenting SERT intrinsic activity, demonstrating mechanistic links between the A3AR and SERT (6). Remarkably, disease-associated alterations in SERT not only implicate SERT activity but also impact SERT regulatory pathways.

Although the etiology of depression is complex and remains unknown, there is a growing body of evidence that depressed subjects display an elevation of pro-inflammatory cytokines, and inflammation plays an important role in the development of depression (7). Viral and bacterial infections that stimulate the production of pro-inflammatory cytokines can produce symptoms of depression (8). The antidepressant-sensitive SERT can be regulated by pro-inflammatory cytokine signaling. Zhu and co-workers have shown that the inflammatory cytokines interleukin-1β (IL-1β) and tumor necrosis factor-α (TNF-α) produce rapid catalytic activation of SERT in cultured 5-HT neurons-derived RN46A cells and mouse nerve terminal preparations in vitro (9). Lipopolysaccharide (LPS) is a component of Gram-negative bacteria outer membrane, which acts as a potent activator of the inflammatory system. It is reported that LPS induces depression symptoms associated with elevations of serum IL-1β in subjects without a psychiatric history (10). It has been demonstrated that LPS binds to toll-like receptor 4 (TLR4) leading to the rapid systemic release of pro-inflammatory cytokines and induces anhedonia in rats and mice (11). Most remarkably, Zhu et al. found that peripheral activation of the innate immune system with LPS leads to a rapid (1 h) stimulation of central nervous system (CNS) SERT activity, accompanied by an acceleration of 5-HT clearance rate and alterations in SERT-dependent behaviors (12). In contrast, another study on the human enterocyte-like Caco-2 cell line have shown that LPS treatment diminished SERT activity and SERT protein level on brush border membrane, and the LPS effect might be due to an alteration of the intracellular traffic of SERT partially mediated by protein kinase C (PKC) activation (13). Therefore, more investigation is needed to provide more information about the effects of LPS on SERT activity and expression.

Using cells derived from rodent mast cells RBL-2H3, the aim of this work was to study the effect of LPS on SERT activity and expression and to determine the intracellular mechanism underlying this effect. Many studies have demonstrated RBL-2H3 cells expressing serotonin synthesis and transporter systems as an ideal model for elucidating the regulatory mechanisms relating to SERT (14-16). Consistent with previous reports, results obtained in our laboratory have shown that the fluorescent styryl dye ASP assay enables the detection of dynamic transport activities of SERT and is amenable for measuring 5-HT uptake (17-21). The results obtained from the present study showed that LPS treatment enhances 5-HT uptake in RBL-2H3 cells in a dose-dependent manner. LPS-induced up-regulation of 5-HT uptake results from the increase in surface-expressed SERT protein, which might be partially mediated by PKG-I and p38MAPK activation following A3 adenosine receptor activation. This finding may contribute to a better understanding of the involvement of the LPS in the pathology and modeling of depression.

2. Materials and Methods

2.1. Reagents and antibodies

ASP (4-(4-(dimethylamino) styryl)-N-methylpyridinium iodide) and Fluo-3/AM were obtained from Invitrogen (Carlsbad, CA, USA); SB203580 and KT5823 were obtained from the Beyotime Institute of Biotechnology (Jiangsu, China). LPS and MRS1191 were obtained from Sigma Chemical Company (St Louis, MO, USA). Primary antibodies against SERT and PKG-I were purchased from Santa Cruz Biotechnology Inc. (Santa Cruz, CA, USA), and those against phosphor-p38MAPK, iNOS were purchased from Cell Signaling Technology (Danvers, MA, USA).

2.2. Cell culture

RBL-2H3 cells were purchased from the China Center for Type Culture Collection (CCTCC; Wuhan, China). RBL-2H3 cells were maintained in nucleoside free Minimum Essential Medium (MEM) α containing 15% fetal bovine serum and were grown into monolayers. Cells were plated on polystyrene tissue culture dishes at densities of 3-10 × 10⁴ cells/mL. After 12 h incubation, cells were replaced with fresh serum-free media. After 4 h, RBL-2H3 cells were incubated in fresh media containing 0.75, 1.5, 3 μg/mL LPS or 0.1% DMSO (as vehicle control) with or without pre-treatment with MRS1191, SB203580 or KT5823.

Primary neuron cultures were prepared from E18 Sprague Dawley rat pups. Animals were treated in accordance with the National Institute of Health Guidelines for the Care and Use of Laboratory Animals. Briefly, tissues were harvested on ice and were washed in D-Hanks Balanced Salt Solution containing 100
IU/mL penicillin, and 100 μg/mL streptomycin, and then mechanically dissociated using trituration and trypsinization. Cells were then seeded onto poly-D-lysine-coated 6-well plates at 2 × 10^6 cells/well in DMEM/F12 media containing B27, L-glutamine, 100 IU/mL penicillin, and 100 μg/mL streptomycin. Neuron cultures were typically grown for 7-10 days.

2.3. Assay for 5-HT uptake

5-HT transport activities were measured using ASP assay on RBL-2H3 cells. Briefly, cells from 80% confluent culture flasks were harvested using 0.25% trypsin and were seeded (35,000 cells per well) into 96-well plates and cultured for 24 h in nucleoside free MEM α containing 15% fetal bovine serum. After 20 h, the media was replaced with serum free media and cells were cultured for 4 h prior to assays. ASP (Invitrogen) dissolved in DMSO was added (final concentration, 1 μM) and incubated in the dark at 37°C for 60 min. Unincorporated ASP was removed by washing (3 times with PBS) and 5-HT transporter activity was quantified according to fluorescence intensities (λex, 475 nm; λem, 605 nm) using a SpectraMax M5 Microplate Reader (Sunnyvale, CA, USA).

2.4. Detection of cytosol Ca\(^{2+}\) using Fluo-3/AM

Detection of intracellular calcium in RBL-2H3 cells was performed using the fluorescent indicator Fluo-3/AM. All images were acquired on a Leica TCS SP5 imaging system mounted on a microscope and an argon ion laser (458-514 nm). Image processing and quantification was carried out using the mean fluorescence intensities of sections acquired.

2.5. NO assay

NO levels were measured with the Griess method using a nitrite detection kit (Beyotime, Jiangsu, China) according to the manufacturer’s instructions. Briefly, 100 μL of medium or standard NaN3 was mixed with 100 μL of Griess reagent in a 96-well plate. After 15 min, optical density was read using a SpectraMax M5 Microplate Reader at 540 nm. Results were calculated for statistical analysis by a standard curve using NaNO2.

2.6. RT-PCR

Total RNA was extracted from cells cultured under different experimental conditions. The extracted RNA (1 μg) was used as a template for first-strand cDNA synthesis using oligo (dT) primers and a modified M-MLV reverse transcriptase (Carlsbad, CA, Invitrogen). Negative amplification control was performed in the absence of reverse transcriptase. One-tenth of the resultant cDNA was used for human TLR4 and human SERT PCR amplification with human β-actin as an internal control. Real-time quantitative polymerase chain reaction (RT-PCR) was performed with the Bio-rad CFX real-time PCR system and β-actin was used as the reference gene. Gene expression was determined using the 2^(-ΔΔCT) method with the following custom designed primers: for β-actin, 5'-AGATCCCTGACCGACGTGGC-3' and 5'-CCAGGGAGGAAGGATGGC-3'; for SERT, 5'-GGTGTGGTAGATGCGCCGCG-3' and 5'-GCTGGGGCGCTCGTCTTTGG-3'.

2.7. Western blot analysis

For surface-localized SERT, the Cell Surface Protein Isolation Kit (Thermo Scientific, Pierce, #89881, Waltham, MA, USA) was used for biotinylation and the isolation of cell surface proteins for western blot analysis. Equal amounts of protein (30 μg) were separated on 12% polyacrylamide gels. Proteins were then transferred to 0.45-μm polyvinylidene difluoride (PVDF) membranes using a Bio-Rad Laboratories Mini Protein system. After treating PVDF membranes with blocking buffer TBS/0.1% Tween20 (TBST) containing 3% BSA for 2 h at 37°C, membranes were incubated overnight at 4°C in TBS buffer containing 3% BSA and primary antibodies against active p38MAPK (1:1000), SERT (1:100), PKG-I (1:100), iNOS (1:1000). Membranes were washed with 3 times in TBST, and were then incubated for 1 h at 37°C with a secondary horseradish peroxidase (HRP)-conjugated antibody at a dilution of 1:1000 in blocking buffer. Finally, membranes were washed extensively in TBST and photographic images were taken after illumination using an enhanced chemiluminescence (ECL) detection reagent. The densitometric analyses of autoradiograms were performed using quantity one software (Bio-Rad Laboratories Inc., Hercules, CA, USA), and data were expressed relative to internal control protein expression.

2.8. Immunofluorescence staining of SERT

Cells were seeded at 5,000 cells per well into 96-well black wall clear bottom plates to receive different experimental treatments. Cells were then fixed in 1× PBS containing 4% paraformaldehyde for 30 min, and were subsequently washed three times with 1× PBS. Fixed cells were then blocked in 1× PBS containing 3% BSA for 10 min. Primary antibodies against SERT and phospho-p38MAPK were applied overnight at 4°C. Cells were then washed three times in PBS and were incubated with fluorescent secondary antibodies at 37°C for 2 h in the dark. Finally, Hoechst 33342 (Molecular Probes) was added (final concentration, 1 μg/mL) for the final 10 min, cells were washed three times in PBS, and then PBS containing 50% glycerol was added. Images were acquired and analyzed using a Cellomics ArrayScan®
VTI Imaging Platform (Thermo Fisher Scientific Inc., Waltham, MA, USA).

2.9. Statistical analysis

All experiments were replicated a minimum of three times. Subsequently, raw data was normalized and exported into GraphPad Prism (GraphPad Software Inc. San Diego, CA, USA) to generate figures. Differences were identified using one- and two-way analysis of variance (ANOVA) with subsequent Dunnett’s comparisons and Student’s t-test. Differences were considered significant when \( p < 0.05 \).

3. Results

3.1. LPS enhanced 5-HT uptake in RBL-2H3 cells in a dose-dependent manner

To examine the effects of LPS on 5-HT uptake, the fluorescent styryl dye ASP was used to detect dynamic transport activities of SERT, and ASP fluorescent intensities in RBL-2H3 cells were monitored after 24 h treatment with LPS. As shown, treatment with 1.5, 3 μg/mL LPS significantly elevated 5-HT transport indicated by increased ASP fluorescence, as readout of SERT activity, in RBL-2H3 cells (Figure 1A), suggesting that...

---

Figure 1. LPS enhanced 5-HT uptake and the level of surface-expressed SERT. (A) RBL-2H3 cells (3.5 × 10⁵ cells/well) were seeded in 96-well microplate and treated with LPS at the indicated concentrations for 24 h before examination. LPS enhanced 5-HT uptake indicated by ASP fluorescence intensity monitored. (B) The mRNA level of SERT was analyzed by real-time PCR following LPS treatment. (C) The protein content of SERT in RBL-2H3 cells was analyzed following LPS treatment. (D) A Thermo Scientific Pierce Cell Surface Protein Isolation Kit (#89881) was used to biotinylate and isolate cell surface proteins for western blot analysis. (E, F) The protein content of SERT in RBL-2H3 cells was confirmed by immunofluorescence analysis following 24 h LPS treatment. Scale bar, 40 μm. Values are expressed as the mean of at least three experiments ± S.E.M; *\( p < 0.05 \), **\( p < 0.01 \) compared to vehicle.
LPS caused dramatic alteration in 5-HT uptake into RBL-2H3 cells in a dose-dependent manner.

3.2. LPS elevated the level of surface-expressed SERT in RBL-2H3 cells and isolated E18 primary rat cortical neurons

The observation of increased 5-HT uptake by LPS treatment in RBL-2H3 cells prompted us to investigate whether LPS induced the alteration in the level of SERT expression. Thus, the transcript level of SERT was determined using quantitative PCR analysis, and the results showed that treatment with LPS did not affect SERT mRNA level compared to vehicle treatment (Figure 1B). Furthermore, western blot analysis on the whole lysate of RBL-2H3 cells demonstrated that LPS did not influence total protein level of SERT, however, level of SERT protein in plasma membrane subfraction prepared from RBL-2H3 cells remarkably increased (Figure 1C). Immunofluorescence analysis using specific SERT antibody showed the protein content of plasma membrane-localized SERT in RBL-2H3 cells significantly increased with mean FI per cell of 286 ± 31 and 311 ± 46 following 24 h LPS treatment compared to 198 ± 23 of vehicle treatment (Figures 1E and 1F). Moreover, we isolated E18 primary rat cortical neurons to further examine the increase in SERT protein level induced by LPS. Representative blot images

Figure 2. LPS elevated NO content and the level of cytosol calcium, and stimulated CaMK-II/iNOS/PKG-I signaling pathway and p38MAPK in RBL-2H3 cells. RBL-2H3 cells (3.5 × 10^5 cells/well) were seeded in 96-well microplate and treated with LPS at the indicated concentrations for 24 h before examination. (A) LPS elevated NO content examined by Griess method. (B) The level of cytosol calcium was determined using Fluo-3/AM following LPS treatment. The phosphorylation of CaMK-II (C), protein level of iNOS (D), PKG-I (E) and active p38MAPK (F) in RBL-2H3 cells was analyzed by western blot following 24 h LPS treatment. (G, H) The activation of p38MAPK in RBL-2H3 cells was examined by immunofluorescence analysis following 24 h LPS treatment. Scale bar, 40 μm. Values are expressed as the mean of at least three experiments ± S.E.M; *p < 0.05, **p < 0.01 compared to vehicle.
demonstrated that 1.5 and 3 μg/mL LPS treatment significantly boosted the expression of surface-expressed protein SERT (Figure 1D). Taken together, these data indicate that although LPS did not affect the total SERT expression, but notably induced the elevation in the plasma membrane distribution of SERT.

3.3. LPS Increased Ca\(^{2+}\) and NO followed by PKG-I/ p38MAPK pathway activation

Increasing evidence indicates that SERT-mediated 5-HT clearance is controlled by multiple pathways that regulate both plasma membrane expression and catalytic activity of SERT (18). Recent studies demonstrate that the up-regulation of SERT activity by serine/threonine kinases, PKG-I and p38MAPK-linked pathways contains increased SERT activation and membrane distribution (22). Thus, Ca\(^{2+}\)-CaMK- II/iNOS-NO/PKG-I and p38MAPK pathway received more attention as one of the most widely studied regulatory mechanisms. In the current study, NO level was firstly determined using Griess method after 24 h treatment with LPS.

Figure 3. LPS-induced 5-HT uptake and surface-expressed SERT in RBL-2H3 cells was hindered by inhibition of PKG-I or p38MAPK. RBL-2H3 cells (3.5 × 10\(^5\) cells/well) were seeded in 96-well microplate and treated with 3 μg/mL LPS for 24 h following 6 h pre-treatment with PKG-I inhibitor KT5823 (2 μM) treatment or p38MAPK inhibitor SB203580 (10 μM). (A-B) Change in 5-HT uptake was determined using ASP assay. (C-D) Representative immunofluorescence images and quantification of SERT expression following 24 h LPS treatment in the presence of PKG-I inhibitor KT5823. (E-F) Representative immunofluorescence images and quantification of SERT expression following 24 h LPS treatment in the presence of p38MAPK inhibitor SB203580. Scale bar, 40 μm. Values are expressed as the mean of at least three experiments ± S.E.M; \(*p < 0.05, **p < 0.01\) compared to vehicle; \(*p < 0.05\) compared to LPS 3 μg/mL treatment.
The results showed that NO levels in RBL-2H3 cells significantly increased when treated with 1.5 and 3 μg/mL LPS (nmol/mg protein: 9.36 ± 0.79 and 10.34 ± 0.65) (Figure 2A). Subsequently, the fluorescent staining using Fluo-3/AM demonstrated that intracellular Ca\textsuperscript{2+} concentration ([Ca\textsuperscript{2+}]\textsubscript{i}) in RBL-2H3 cells was lifted by LPS treatment up to 2-fold of that in vehicle treated cells (Figure 2B). Western blot analysis indicated that phosphorylated CaMK-II, protein level of iNOS and PKG-I as well as active p38MAPK were markedly elevated (Figures 2C-2E). Consistent with the data shown above, immunofluorescence staining using anti-phosphorylated p38MAPK further confirmed the almost 1.6-fold increase in the level of active p38MAPK by LPS treatment (Figures 2F and 2G). Taken together, these data suggest that Ca\textsuperscript{2+}-CaMK-II/iNOS-NO/PKG-I and p38MAPK signaling might be implicated in the up-regulation of SERT by LPS.

3.4. The Effect of PKG-I or p38MAPK inhibition on LPS-induced 5-HT uptake and SERT expression in RBL-2H3 cells

To clarify the involvement of PKG-I or p38MAPK in LPS-induced 5-HT uptake and SERT expression, here, PKG-I inhibitor KT5823 or p38MAPK inhibitor SB203580 was respectively pretreated to RBL-2H3 cells to investigate their influences on LPS profile. The assay for 5-HT uptake using ASP transport demonstrated that PKG-I inhibitor KT5823 (2 μM) or p38MAPK inhibitor SB203580 (10 μM) pretreatment did not notably affected the 5-HT uptake, however, 3 μg/mL LPS-induced increase in the 5-HT uptake was remarkably impaired in the presence of the two inhibitors (Figures 3A and 3B). The immunofluorescence assay labeling SERT indicated that as compared to control treatment with just 3 μg/mL LPS, the protein level of SERT in the surface of RBL-2H3 cells markedly declined when treated with 2 μM PKG-I inhibitor KT5823 followed by 3 μg/mL LPS treatment for extra 24 h (Figures 3C and 3D). The fluorescence intensities of surface-localized SERT in RBL-2H3 cells co-treated with 3 μg/mL LPS and 10 μM p38MAPK inhibitor SB203580 also significantly fell into decline. Therefore, these results suggest that PKG-I and p38MAPK activation play a crucial role in the LPS-induced 5-HT uptake and SERT expression in RBL-2H3 cells.

3.5. Effect of Adenosine 3A Receptor (A3AR) antagonism on LPS-induced 5-HT uptake and SERT expression in RBL-2H3 cells

It is reported that the activation of A3AR results in increased 5-HT uptake in RBL-2H3 cells and that A3AR regulates serotonin transport via NO and cyclic guanosine monophosphate (cGMP) (22,23). Thus, it is necessary to dig out the role of A3AR in the LPS-induced 5-HT uptake and SERT expression. RBL-2H3 cells were pre-treated with an A3AR antagonist MRS1191 (200 nM) for 6 h, followed by treatment with 3 μg/mL LPS. After 24 h of incubation, the change in the 5-HT uptake was assessed as described previously, and we observed that the addition of MRS1191 notably disrupted the effects exerted by 3 μg/mL LPS (Figure 4).
4A). Immunofluorescence assay also showed that there was no remarkable difference between vehicle and MRS1191 treatment, however, level of surface-expressed SERT was significantly higher (316 ± 27) of 3 μg/mL LPS treatment than that of co-treatment with 200 nM MRS1191 and 3 μg/mL LPS (245 ± 31) (Figures 4B and 4C), indicating that the activation of A3AR was implicated in LPS-induced upregulation of 5-HT uptake and SERT expression in RBL-2H3 cells.

4. Discussion

In the present study, we showed that 24 h treatments with LPS significantly increased the 5-HT uptake and plasma membrane expression of SERT in a rat basophilic leukemia cell line RBL-2H3 cell. Moreover, elevation in NO content and intracellular Ca²⁺ concentrations was observed following LPS treatment. Mechanistic investigation showed that LPS induced CaMK-II/iNOS/PKG-I and p38MAPK signaling pathways, leading to an increase in the activation and plasma membrane distribution of SERT. Furthermore, the effects of LPS on SERT were impaired by the presence of A3AR antagonist MRS1191.

In our experiments, we found that LPS significantly increased the 5-HT uptake and upregulated the protein level of SERT in RBL-2H3 cell, as contrast to the previous report on the human enterocyte-like Caco-2 cell line (13). Although Caco-2 expresses the human SERT, this cell line lacks in serotonin synthesis and discretion. Comparatively, rat basophilic mast cells RBL-2H3 express not only transporter systems but also serotonin synthesis, and are regarded more relative to the physiology of 5-HT neurons. Miller and Hoffman first provided evidence of adenosine receptor (AR) regulation of SERT using this cell line (22). Kim et al. investigated the molecular mechanisms of antidepressant drugs that sertraline up-regulates tryptophan hydroxylase expression and serotonin synthesis in RBL-2H3 cells (24). These studies proved RBL-2H3 cells as an ideal model for studying the SERT. In addition, SERT is also widely expressed in the front cortices of the brain and the hippocampus which are closely associated with the pathogenesis of depression (23,25), so we verified the effects of LPS in isolated E18 primary rat cortical neurons and gained the same observation.

It is believed that lipopolysaccharide activity is mediated by TLR 4 activation and a cascade of intracellular reactions which involves different signalling pathways including p38 MAPK, protein kinase A (PKA) and PKC (26). It has been reported that interleukin-1β (IL-1β) and TNF-α stimulation of SERT activity in vitro is mediated through the activation of p38 MAPK (9). Since LPS tightly correlates to these pro-inflammatory cytokines, we examined the requirement for p38 MAPK in SERT modulation exerted by LPS using treatment with p38 MAPK inhibitor SB203580. The observation that active p38 MAPK increased with LPS treatment and the SERT up-regulation by LPS was impaired by treatment with SB203580 indicates that p38 MAPK may act as an activator of SERT function.

Increasing evidences indicate that SERT are tightly controlled by multiple signaling pathways including
G-protein coupled receptors-linked pathways and various kinases as well as their substrates (27-31). Recently, Miller et al. showed that the activation of A3AR results in increased 5-HT uptake in RBL-2H3 cells and that A3AR regulates serotonin transport via NO and cGMP (22). Some in vitro studies have revealed multiple second messengers or second messenger-linked kinases participate in acute SERT regulation (32). Experiments with synaptosomes and cells demonstrate that SERT activity decreases after depletion of intracellular Ca2+, treatment with calmodulin inhibitors and phorbol esters (33,34). PKA, PKC and PKG activation have also been demonstrated to impose post-translational regulation on SERT by phosphorylation, possibly reflecting the heterologous context of SERT expression. Zhu et al. have reported that involvement of A3AR in serotonin transporter trafficking and activation in RBL-2H3 cells and SERT stimulation by A3AR requires activation of PKG by a phospholipase C, Ca2+, NOS and cGMP-dependent mechanism (14,27). In the present study, we provided evidence that Ca2+-CaMK-II/iNOS/PKG-I signaling pathways contribute to up-regulation of SERT in RBL-2H3 cells by LPS. This effect maybe partially mediated through activates A3AR by LPS (Figure 5). Although the potential mechanism by which LPS enhances activates A3AR in RBL-2H3 cells remains unclear, this finding offers a novel insight into the modulation of SERT. Moreover, many researches are still needed to clarify the interaction between A3AR and LPS.

In conclusion, the present experiments demonstrate that LPS enhances the 5-HT uptake and transposition from cytosol to plasma membrane of SERT in RBL-2H3 cells, and the underlying mechanism involves CaMK-II/iNOS/PKG-I and p38 MAPK activation following calcium flux, which may be partially mediated by A3AR activation. LPS-induced alteration possibly provides a powerful tool to model the pathology of depression and the discovery of new antidepressant.

Summary This study demonstrated that ARID5B mRNA is present in mouse cardiomyocyte HL-1 cells, and that ARID5B siRNA constantly knocked down ARID5B gene expression to the 40% level of control. AMPKα2 protein was elevated in such ARID5B knockdown HL-1 cells, and this was accompanied by an increase in the level of phosphorylated AMPKα. Since AMPKα2 mRNA levels did not change in ARID5B knockdown cells, the stability of AMPKα2 protein was investigated using inhibitors for protein synthesis and proteasomal degradation. Treatment of HL-1 cells with either cycloheximide or MG132 caused an appreciable increase in the amount of AMPKα2 protein in ARID5B knockdown cells, which suggests that knockdown of ARID5B mRNA extends the half-life of AMPKα2 protein in HL-1 cells via yet unidentified mechanisms. As for the expected downstream consequences of AMPKα2 activation, we found thus far that glucose uptake, fatty acid uptake, or fatty acid oxidation remained unchanged in HL-1 cells after knockdown of ARID5B. Further studies are required to understand the mechanisms for ARID5B knockdown and resulting AMPKα2 activation, and also to identify which metabolic pathways are affected by AMPKα2 activation in these cells. In summary, this study provided the foundation for an in vitro cell culture system to study possible roles of ARID5B in cardiomyocytes.

Keywords: Mrf-2, ARID5B, downregulation by siRNA, AMPKα2 activation, cardiac myocytes, HL-1 cells

1. Introduction

ARID5B (AT-rich interaction domain-containing protein 5B) was previously known as Mrf-2 (modulator recognition factor 2). It was identified in our laboratory in 1996 as a novel nuclear protein that binds to sequences upstream of the human cytomegalovirus major immediate-early enhancer/promoter and exerts repressor activity in undifferentiated human Tera-2 cells (1). Subsequent studies revealed the three-dimensional structure of the novel DNA-binding motif (ARID) of Mrf-2 and mechanisms of DNA recognition (2-4). The ARID family of DNA-binding proteins has grown since then to include fifteen proteins found in humans and most other vertebrate species, and six proteins found in Drosophila as well as proteins found in worms, fungi, plants and yeast (5-8). The ARID family is divided into six sub-families. In addition to a variety of roles as transcription factors in cell growth, differentiation, and development (6), a number of studies have suggested that proteins in most of the ARID sub-families are involved in cancer as tumor suppressors or promoters (8). A notable exception is the ARID5 sub-family which consists of two members, Mrf-1/ARID5A and Mrf-2/ARID5B (7,8). Mrf-2/ARID5B is expressed in various tissues including mouse cardiac and vascular tissues, where it seems to regulate smooth muscle cell differentiation and proliferation (9), lung, kidney, and brain as well as less abundantly in adrenal gland, spleen and thymus (10). Important roles of ARID5B in growth, immune, and sexual development have been
MEFs derived from postnatal life. Studies using mouse embryonic fibroblasts (MEFs) derived from ARID5B embryos and ARID5B+/- littermate controls demonstrated that adipogenesis in ARID5B+/- MEFs was significantly lower than that in ARID5B+/- MEFs, but was restored when ARID5B was expressed in ARID5B+/- MEFs (14). Similarly, the expression of multiple adipogenic genes was inhibited following transient transfection of siRNA targeting ARID5B in 3T3-L1 cells (14). Since a role of ARID5B in the regulation of metabolism has been suggested (11-13), we investigated the potential involvement of ARID5B and AMP-activated protein kinase (AMPK) in the metabolism of cardiac myocytes.

AMPK has been known as a sensor and regulator of energy balance at the cellular level as well as at the whole body level by responding to hormonal and nutrient signals (15-17). Multiple AMPK subunit isoforms encoded by distinct genes were identified with two α subunits (α1 and α2), two β subunits (β1 and β2), and three γ subunits (γ1, γ2, and γ3) (15,16). The α subunit is a kinase which is activated by phosphorylation in response to an increase in the AMP:ATP ratio. Binding of AMP to the γ subunit of the AMPK αβγ complex induces conformational changes in the α subunit kinase leading to the critical Thr172 phosphorylation by its upstream kinases. Although the mechanisms of these signaling pathways are not fully understood, it has been well-documented that activation of AMPK in skeletal and cardiac muscles is induced by metabolic stress and whole-body energy status as well as the AMPK mimetic AICAR and diabetic drugs such as metformin (15,18,19).

Previous studies showed that AICAR increased glucose uptake in heart muscle, indicating that AMPK may be involved in GLUT4 translocation (20), and that AMPK and PI-3K/Akt had an additive effect on oxidative stress-mediated GLUT4 translocation in cardiac myocytes (21). Furthermore, mice lacking AMPKa2 or expressing dominant negative AMPKa2 inhibited the ischemia-induced stimulation of glucose uptake in cardiac myocytes (22-24). These studies strongly suggested that AMPKa2 plays an important role in regulating cardiac glucose metabolism and protecting the heart from metabolic stresses.

The current study tested the hypothesis that ARID5B plays a role in glucose metabolism via the AMPK signaling pathway in cardiac myocytes. We found that when siRNA was introduced to HL-1 cardiomyocytes, ARID5B mRNA was significantly reduced, and that the levels of both total and phosphorylated AMPKa2 subunit were significantly increased. The mechanism and functional consequences of the AMPKa2 activation induced by ARID5B knockdown in HL-1 cells were also investigated. Although not conclusive, this study provided a good model system for further studying the role of ARID5B knockdown in AMPKa2 signaling pathways.

2. Materials and Methods

2.1. Materials

Mouse HL-1 cardiomyocytes were provided by Dr. W. Claycomb (Louisiana State University Health Science Center, New Orleans, LA) (25,26). Claycomb medium, fetal bovine serum (FBS), penicillin-streptomycin, norepinephrine, L-glutamine, trypsin-EDTA, trypsin inhibitor, fibronectin, cytochalasin B, cycloheximide, and MG132 were purchased from Sigma-Aldrich. L-Ascorbic acid sodium salt was from Mallinckrodt. Opti-MEM and Lipofectamine® RNAiMAX Transfection Reagent were from Life technologies. Bacto gelatin, ON-TARGETplus Mouse ARID5B siRNA-SMART pool (siRNA), ON-TARGETplus Non-targeting Pool (control scramble RNA), Tris-HEPES gels, and 20× Tris-HEPES buffer for sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) were obtained from Thermo Fisher Scientific. Polyvinylidene difluoride (PVDF) membrane was from GE Healthcare Life Sciences. 10× TBS was from Bio-Rad. Non-fat milk was from Labscientific, Inc. HyGLO Chemiluminescent HRP Antibody Detection Reagent was from Denville Scientific Inc. 2-Deoxy-D-[3H]glucose and [3H]palmitic acid were from American Radiolabel Chemicals.

2.2. Cell culture

HL-1 cells were grown as monolayer cultures in flasks, dishes, and plates precoated with 2 μg/cm² fibronectin dissolved in 0.02% gelatin. HL-1 cells were maintained in Claycomb medium supplemented with 10% FBS, 2 mM L-glutamine, 0.1 mM norepinephrine (prepared freshly from 10 mM stock solution in 30 mM L-ascorbic acid), and 100 μg/mL penicillin-streptomycin. Cells were grown at 37°C in an atmosphere of 5% CO2. The medium was changed every other day.

2.3. siRNA transfection

The transfection procedure is summarized in Figure 1. We used a commercially-available mixture of four double-stranded siRNAs with the following sequences on the sense strand: 5’-acaauaagugacgguaa-3’,
5'-guguagaguucgccccaaa-3', 5'-cggagaaguccggcagucu-3', and 5'-guguacaguuaaagccgau-3'. These siRNA's target exons 5, 4-plus 5, 10, and 4, respectively of ARID5B. Cells were seeded in 24-well plates, 12-well plates, or 35 mm dishes (2.5 × 10^4 cells/cm^2), and transfected 24 h after seeding. At that time (40-50% confluence), the cells were incubated for 2-3 h in Claycomb medium without penicillin and streptomycin, then transfected with 50 nM siRNA or control scramble RNA using Lipofectamine® RNAiMAX Transfection Reagent. After 24 h, the medium was replaced by Claycomb medium without penicillin and streptomycin. Cells were used for molecular and cellular experiments at 48 h post-transfection. To confirm the effect of siRNA, cells were lysed with 700 μL of QiAzol (Qiagen), and RNA was isolated with Qiagen RNeasy®. ARID5B mRNA level was determined by quantitative real-time PCR as described in section 2.4.

2.4. Quantitative real-time PCR

Total RNA samples (1 μg) were reverse-transcribed with High-Capacity cDNA Reverse Transcription Kit (Life technologies), and the resulting cDNA samples were amplified with the specific primer pairs for mouse ARID5B and Rpl19 as a control housekeeping gene using iQ SYBR Green Super Mix (Bio-Rad). The sequences of specific primer pairs used were as follows. ARID5B forward, 5'-aagaaaaacgcccatcgagc-3'; reverse, 5'-ctcccaggattaccacctaac-3'; Rpl19 forward, 5'-agcctgtgactgtccattcc-3'; reverse, 5'-ctcccaggattaccacctaac-3'. The reaction was performed using the following temperature cycles, initial denaturation at 95°C for 10 min followed by 40 cycles of amplification at 95°C for 10 sec and 56°C for 30 sec (ARID5B), or 40 cycles of amplification at 95°C for 10 sec and 61°C for 30 sec (Rpl19). The mRNA expression level was determined using the CFX96 real-time detection system (Bio-Rad). Relative gene expression was calculated using the ΔΔCT method.

2.5. Western blotting analysis

At 48 h post-transfection, cells were washed twice with ice-cold PBS and lysed using ice-cold cell lysis buffer (50 mM HEPES, pH 7.4, containing 2 mM Na2VO4, 10 mM Na3P04, 10 mM NaF, 2 mM EDTA 2Na, 2 mM EGTA, and 0.2 mM PMSF). After incubation on a shaker for 15 min at 4°C, cell lysates were centrifuged at 14,000 rpm at 4°C for 15 min. Protein concentrations in the cleared lysates were measured by BCA assay (Thermo Fisher Scientific). Samples of 10-20 μg were subjected to SDS-PAGE using Tris-HEPES gels and then transferred to PVDF membranes. The membranes were blocked with 5% non-fat milk in TBST buffer (TBS containing 0.1% Tween 20) for 1 h at room temperature. After blocking, membranes were incubated at 4°C overnight with the following primary antibodies; anti-phospho-AMPKα (1:1000, #2535) and anti-AMPKα (1:1000, #2603) from Cell Signaling Technology, anti-AMPKα2 (1:1000, ab97275) from Abcam, anti-EFTUD2 (1:2000, 10208-1-AP) from Proteintech, and anti-GAPDH (1:10000, AM4300) from Ambion. Subsequently, the membranes were washed 3 times with TBST for 5 min and incubated with HRP-conjugated anti-rabbit IgG (#170-6515, Bio-Rad) or HRP-conjugated anti-mouse IgG (sc-2005, Santa Cruz) for 1 h at room temperature. Then, the membranes were washed 4 times with TBS containing 0.1% Tween 20 and 0.1% Triton X-100 for 5 min at room temperature, then incubated with HyGLO Chemiluminescent HRP Antibody Detection Reagent. The membranes were exposed to X-ray film, and the protein bands on the films were quantified using Image J software.

2.6. Analysis of AMPKα2 protein stability

HL-1 cells in 35 mm dishes were transfected with siRNA as described in section 2.3, and at 48 h post-transfection, the growth medium was changed to medium containing 5 μg/mL cycloheximide (CHX) or 10 μM MG132, a proteasomal degradation inhibitor. Cells were harvested at different time points after CHX or MG132 treatment, and AMPKα2 and GAPDH protein levels were determined by Western blotting.

2.7. Glucose and fatty acid uptake assays in HL-1 cells

Cells were grown in 24-well plates and transfected with siRNA as described in section 2.3. Cells were washed with KRPH buffer (130 mM NaCl, 4.7 mM KCl, 1.24 mM MgSO4, 2.5 mM CaCl2, 1 mM HEPES, 2.5 mM NaH2PO4) once at 48 h post-transfection. Then cells were incubated in 250 μL of fresh KRPH buffer for 15 min at 37°C. For the glucose uptake assay, HL-1 cells were incubated with [3H]2-deoxy-D-glucose (10 μM; 137.5 μCi/well) for 10 min at 37°C. The incubation medium was aspirated, then the cells were washed four times with ice-cold PBS and solubilized by adding 100 μL of 0.5 M NaOH to each well. Aliquots of the cell extracts were transferred to vials for scintillation counting. In order to determine the level of non-specific background, cells in replicate wells were pretreated with 20 μM cytochalasin B for 15 min at 37°C, incubated with [3H]2-deoxy-D-glucose, and processed in the same way. Aliquots of the same cell extracts were used for determining protein concentrations by BCA assay. Results were calculated as pmol of glucose uptake per min per mg of protein.

For fatty acid uptake assays, cells were incubated for 15 min at 37°C in KRPH buffer, and [3H] palmitic acid (40 μM; 10.5 μCi/well) was added to each well. After a 20 min-incubation at 37°C, the medium was removed, the cells were washed 4 times with ice-cold
PBS, and solubilized with 100 μL of 0.5 M NaOH per well. The radioactivity in both the incubation medium and the cell lysate from each well were measured by scintillation counting. The percentage of fatty acid uptake was calculated by dividing $^3$H in the cell lysate by total $^3$H from both the cell lysate and incubation medium.

2.8. Positron Emission Tomography (PET) for glucose uptake in the heart of ARID5B knockout mice

Animal studies were approved by the City of Hope Animal Care and IACUC. Generation of the total body ARID5B knockout mice has been previously described (13). Mice were housed in a temperature-controlled environment with a 12 h light: 12 h dark cycle and allowed ad libitum access to standard chow and water.

Thirty two week-old male mice were used for these experiments. The $^{18}$F-flurodeoxyglucose ($^{18}$F-FDG) radio-tracer was obtained from the City of Hope radio-pharmacy. The mice were imaged at the City of Hope Small Animal Imaging Core on two days: On the first day, two ARID5B$^{-/-}$ males and one ARID5B$^{+/+}$ male littermate control were imaged; on the second day, one ARID5B$^{-/-}$ male and two ARID5B$^{+/+}$ male littermate controls were imaged. The average weight for the ARID5B$^{-/-}$ males was 25.7 ± 4.0 grams; the average weight for the ARID5B$^{+/+}$ males was 41.3 ± 4.1 grams ($p < 0.05$). Prior to imaging, the mice were placed in individual cages with Sani-chip bedding, and fasted overnight (from 5:30 PM to 9:00 AM). The mice were placed in a cage with a warming light for 15 min prior to injection via the tail vein with 121-177 μCi of $^{18}$F-FDG, and then moved to cages without warming lights for uptake periods of 58-60 min. Following the uptake period, tail regions of the mice were imaged for 2 min to insure that there was no extravasation of the tracer from the injection site. The mice were imaged for 10 min while under isoflurane anesthesia. Following the imaging scans, the mice were euthanized under isoflurane, and various organs and tissues were harvested. The tissue samples were weighed, and the $^{18}$F in each sample was measured using a gamma counter. The CPM values were corrected for the radioactive decay that occurred in the interval following the injection. Imaging data were analyzed using the ASI-Pro software package. Specific uptake values in the heart were estimated as follows. The PET images were rotated so that a series of transverse optical sections of the heart could be analyzed. In each optical section both the heart plus the enclosed blood space and the blood space alone were analyzed by defining the appropriate regions of interest. The volume of heart tissue was calculated as the volume of heart-plus-blood minus the volume of blood alone. Similarly, the total DPM of $^{18}$F per cc in the heart was as calculated by subtracting the blood space values from the heart-plus-blood space values. Specific uptake values are expressed as (DPM/cc tissue)/(injected dose in μCi/ml blood). The blood volume was calculated as 5.85% of total body weight.

2.9. Statistics

Data are expressed as mean ± SEM. Differences were evaluated by two-tailed Student $t$ test. Statistical significance was set at $p < 0.05$.

3. Results

3.1. ARID5B gene expression was reduced in HL-1 cardiomyocytes by siRNA

The siRNA transfection protocol as schematically illustrated in Figure 1 was used throughout this study.

![Figure 1. Schematic diagram of the siRNA transfection protocol used in this study. HL-1 cardiomyocytes were seeded in 24-well plates, 12-well plates, or 35 mm dishes with a density of 2.5 × 10^4 cells/cm^2. Cells were cultured for 24 h to reach 40-50% confluence (inset, left panel) before transfection of siRNA or control scramble RNA as described in Methods. At 24 h post-transfection (inset, right panel), the medium was replaced with fresh medium to allow HL-1 cells to recover. At 48 h post-transfection, cells were subjected to various analyses.](www.biosciencetrends.com)
HL-1 cardiomyocytes were cultured for 24 h to allow them to attach to the plates (Figure 1 insets, left panel) before being treated with siRNA or scramble RNA for 24 h. The transfection medium was replaced with fresh culture medium and the resulting HL-1 cardiomyocytes were subjected to cellular and molecular analyses at 48 h post-transfection (Figure 1 insets, right panel).

In each experiment, the level of ARID5B expression in HL-1 cells was determined by quantitative real-time PCR. The results of nine independent experiments showed that the mRNA level in cells treated with ARID5B siRNA was always ~38% of the value for cells treated with control scramble RNA (Mean ± SE: 37.7 ± 2.1 %, n = 9, p < 0.001). Results of representative experiments are shown in Figures 2A, 3A, 4A, and 5A. This indicates not only that ARID5B mRNA is present in HL-1 cells, but also that siRNA efficiently knocked down gene expression.

3.2. Both AMPKα2 protein and AMPKα phosphorylation levels were elevated by knockdown of ARID5B mRNA

After confirming siRNA downregulated ARID5B mRNA (Figure 2A), we determined AMPKα protein levels by Western blotting. As seen in Figure 2B, Western blotting analysis of cell lysates with anti-AMPKα1 or anti-AMPKα2 antibody clearly showed that the AMPKα2 protein level was significantly increased in cells transfected with ARID5B siRNA, but that no change was observed in the AMPKα1 protein level (Figure 2B). Quantitation of immunostained bands from four experiments revealed an average increase of 1.4-fold (1.4 ± 0.15, n = 4, p < 0.05) in AMPKα2 protein level (Figure 2C, right panel) but no change in the AMPKα1 protein level (Figure 2C, left panel).

The phosphorylation status of T172 of AMPKα was also determined by Western blotting using anti-phospho AMPKα. This monoclonal antibody was produced by immunizing animals with a synthetic phospho-peptide corresponding to amino acid residues surrounding Thr172 of human AMPKα protein. Because this amino acid sequence is conserved between mouse and humans and between AMPKα1 and AMPKα2 in both species, the antibody recognizes phospho-Thr172 in both AMPKα1 and AMPKα2. Thus, in order to assess AMPKα phosphorylation, the levels of total AMPKα protein (AMPKα1 plus α2)
and the combined levels of phosphorylated AMPKα1 plus α2 were measured by Western blotting. Figure 2D clearly shows an increase in the amount of total AMPKα protein. Since the experiments shown in Figures 2B and 2C indicate that AMPKα2 increases while AMPKα1 does not, it is clear that the increase in total AMPKα protein is due solely to the increase in AMPKα2. Figure 2E (right panel) revealed the increase in total AMPKα (1.4 ± 0.13-fold, \( n = 4 \), \( p < 0.05 \)) is also significant and even greater than the increase in total AMPKα. Although other possibilities must be considered, these results, taken together, strongly suggest that ARID5B knockdown resulted in the increase in AMPKα2 protein and in phospho-AMPKα2, which is indicative of AMPKα2 activation.

### 3.3. Knockdown of ARID5B mRNA extended the half-life of AMPKα2 protein

In order to understand the mechanisms by which ARID5B knockdown increases AMPKα2 levels, we first compared AMPKα2 mRNA levels in cells transfected with siRNA or control scramble RNA. The results showed no difference (data not shown), which suggested that ARID5B is not involved in transcriptional regulation of AMPKα2. Next, we investigated the stability of AMPKα2 protein. Cells transfected with siRNA or control scramble RNA (Figure 3A) were subjected to treatment with cycloheximide (CHX) or MG132, and their effects on inhibition of AMPKα2 protein synthesis or proteasomal degradation were measured. A representative result from two CHX experiments is shown in Figures 3B and 3C. In the absence of CHX, the level of AMPKα2 protein was elevated by ARID5B knockdown HL-1 cells by more than 2-fold (compare Figure 3B lanes 1 and 5). In the presence of CHX the level of AMPKα2 protein declined rapidly at 30 min, then recovered slowly over the next 2 h in the control cells (Figure 3B lanes 1-4). In contrast, the levels of AMPKα2 protein remained elevated in ARID5B knockdown cells for 1 h, even when compared to the levels of AMPKα2 protein in control cells in the absence of CHX (compare Figure 3B lanes 1 to lanes 6 and 7). These results suggest that AMPKα2 protein appears more stable when ARID5B mRNA level is reduced.

When cells were treated with 10 μM MG132, a slight increase in AMPKα2 protein was seen in the control cells after 4 and 8 h-incubation (Figures 3D and 3E). This indicated that AMPKα2 protein is being accumulated in HL-1 cells due to the inhibition of proteasome-mediated protein degradation as expected. In siRNA-transfected cells, a significant elevation of AMPKα2 protein (an average of 4-fold at 0 h) was observed, again confirming the results described in section 3.2. The effect of MG132 was also seen in an accumulation of AMPKα2 protein after 4 or 8 h-incubation but to a lesser extent (Figures 3D and 3E), which may indicate that the AMPKα2 protein expression had already saturated at 0 h of MG132 treatment in cells when ARID5B mRNA was knocked down.

The results shown in Figure 3 thus suggested that knockdown of ARID5B mRNA most likely extended the half-life of AMPKα2 protein. It remains to be answered how ARID5B controls the stability of AMPKα2 protein.
In order to investigate whether a decrease in AMPK increases glucose uptake. Specifically, activation of AMPK via AICAR increased glucose uptake in ARID5B knockdown HL-1 cells and hearts of ARID5B knockout mice.

Next, we investigated possible physiological consequences of high levels of activated AMPKα2 protein which is considered to be a sensor and regulator of energy balance at the cellular level. Since AMPKα2 activation clearly occurs in the ARID5B knockdown cells, glucose uptake, one of possible physiological change, was measured in cells transfected with siRNA and control scramble RNA. The results, which are summarized in Figures 4A and 4B, did not show any significant differences in glucose uptake in those cells, however. Glucose uptake in HL-1 cardiomyocytes did respond to the AMPK mimetic AICAR which we used for control experiments. When added at 0.5 mM to the media 1 h prior to glucose uptake experiments, AICAR stimulated glucose uptake in non-treated and scramble RNA-treated cells increased 1.2 ± 0.13 (n = 3, p > 0.05) and 1.3 ± 0.03 (n = 3, p < 0.01)-fold, respectively. These effects, though small, positively demonstrated the correlation of glucose uptake and AMPK activation in HL-1 cells.

In order to investigate whether a decrease in AMPKα2 protein levels was elevated in ARID5B knockdown. No difference in fatty acid uptake was, however, observed between control and ARID5B knockdown HL-1 cells (Figure 5).

4. Discussion

We demonstrated that siRNA efficiently knocked down ARID5B gene expression (to an average of 38% of control levels) in mouse cardiomyocyte HL-1 cells. AMPKα2 protein levels were elevated in ARID5B knockdown HL-1 cells, and this was accompanied by an increase in the phosphorylation of AMPKα2. Thus, in short, this study provided the foundation for an in vitro cell culture system to study possible roles of ARID5B in cardiomyocytes. This experimental in vitro cell culture may be useful in studying cardiac metabolism in pathophysiological conditions such as diabetic cardiomyopathy (28).

ARID5B expression affects glucose uptake in live animals, positron emission tomography (PET) for glucose uptake in the hearts of wild-type and ARID5B knockout mice (n = 3) was performed. Although some tendency of a slight increase was observed in glucose uptake in the hearts of ARID5B knockout mice as compared to that in the hearts of wild type mice, the difference was not statically significant (Figure 4C).

3.5. Fatty acid uptake in ARID5B knockdown HL-1 cells

Generally speaking, the adult heart utilizes fatty acids as its main energy source (27). Thus, it can be speculated that fatty acid utilization may be affected by ARID5B knockdown. No difference in fatty acid uptake was, however, observed between control and ARID5B knockdown HL-1 cells (Figure 5).
heart muscle (20) and in cardiac myocytes (21). Mice lacking AMPKα2 or expressing dominant negative AMPKα2 showed an inhibition of ischemia-induced stimulation of glucose uptake in cardiac muscle (22-24). In HL-1 cells it has been shown that insulin or the AMPK activator oligomycin stimulated glucose uptake by inducing translocation of GLUT4 (30). Adiponectin treatment also enhanced glucose and fatty acid uptake in HL-1 cells, and these effects were accompanied by increased AMPK phosphorylation (31). Based on previous reports, AMPKα2 activation in ARID5B knockdown HL-1 cells would be expected to result in increase in glucose and/or fatty acid uptake. When the functional consequences of the AMPKα2 activation induced by ARID5B knockdown in HL-1 cells were evaluated, however, under the culture conditions used in this study, we did not observe changes in glucose uptake (Figure 4), glycolysis (data not shown), fatty acid uptake (Figure 5), and fatty acid oxidation (data not shown). Further studies are obviously required to identify which metabolic pathways are affected by AMPKα2 activation in HL-1 cells.

Since AMPKα2 mRNA levels were not affected by ARID5B knockdown in HL-1 cells, the stability of AMPKα2 protein was investigated using an inhibitor of protein synthesis (CHX) and an inhibitor of the proteasome degradation pathway (MG132). AMPKα2 protein levels remained significantly elevated for an hour following CHX treatment in ARID5B knockdown HL-1 cells, while AMPKα2 protein levels fell dramatically in control cells. These results indicated that ARID5B knockdown extends the half-life of AMPKα2 protein in HL-1 cells. On the other hand, MG132 increased AMPKα2 protein levels three-fold in control cells, but had no effect in ARID5B knockdown HL-1 cells. It should be noted that the level of AMPKα2 protein in MG132-treated control cells was only half that of untreated ARID5B knockdown cells, even after eight hours of treatment. Wang et al. showed that calorie restriction (CR) increased the protein level of AMPKα2 and phosphorylation of AMPKα2 in skeletal muscle of wild-type mice, and that these changes in skeletal muscle contributed to an increase in whole body insulin sensitivity (32). CR did not increase insulin sensitivity in AMPKα2-/- mice. They also demonstrated that CR serum increased the stability of AMPKα2 protein in C2C12 myoblasts by inhibiting ubiquitination of AMPKα2 (32). Another study showed that life-long CR elicits a myocardial phenotype that is profoundly protected against ischemia/reperfusion injury, and that AMPK activation may play an important role in this process (33). It has been suggested that ubiquitination of AMPK in the heart may play a significant role in the etiology of cardiac diseases, and that this process presents an attractive target for developing novel therapies (34). In this regard, our finding that ARID5B may de-stabilize AMPKα2 protein in cardiomyocytes is intriguing. Whether or not the regulation of AMPK by ubiquitination is involved in this phenomenon requires further investigation.

In summary, this study provided the foundation for an in vitro cell culture system to study possible roles of ARID5B in cardiomyocytes. Further studies are required to understand the link between ARID5B knockdown and resulting AMPKα2 activation and the possible involvement of the ubiquitin proteasome system in AMPKα2 activation.

Summary
To investigate C35 protein expression in breast carcinoma and to investigate its clinicopathological significance, a total of 68 cases of breast carcinoma and 20 cases of normal breast tissue samples were obtained from the clinic. Protein expression of C35, ER, PR and HER-2 were determined using immunohistochemistry. The correlations between C35 expression and clinicopathological parameters were analyzed on the basis of individual clinicopathologic records. Overexpression of C35 was detected in 56 of 68 (82.35%) breast carcinoma samples and only 3 of 20 (15%) normal breast tissue samples, and frequency of C35 expression was significantly associated with clinical Tumor Node Metastasis staging and Scarff-Bloom-Richardson grade (p < 0.05), but was not related to patients age, menstrual status and tumor diameter. C35 expression was positively related with the expression of HER-2 (r = 0.207), whereas negatively related with the expression of ER and PR. Further, C35 was prevalent in all four molecular subtypes of breast carcinoma with no significant difference of expression frequency. However, they have significant differences in lymphatic metastasis cases compared to the non-metastasis cases (p < 0.05). Since C35 protein was extensively expressed in all stages of breast carcinoma, and was closely associated with tumor progression and lymph node metastasis, it might be used as a reliable biomarker or therapeutic target for diagnosis and treatment.

Keywords: C35, breast carcinoma, biomarker, expression, clinicopathologic correlation

1. Introduction
Breast carcinoma (BC) is the most common malignant cancer in women living in China at present. According to the statistics from the Fan et al. report published in 2014, the incidence of BC in China is increasing rapidly, more than 1.6 million people were diagnosed and 1.2 million people died of BC each year, and the newly diagnosed cases account for 12.2% (1). The increasing incidence of BC is associated with the residents increasing socioeconomic status and unique reproductive patterns. Additionally, higher incidence and younger patients occur in high-income cities such as Beijing, Shanghai and Tianjin (2). Notably, delays in diagnosis and inherent subjectivity involved in histopathology lead to a more advanced stage of this disease, thus effective biomarkers are introduced into the clinic to improve tumor classification and diagnosis of this disease.

Currently, three molecular biomarkers progesterone (PR), estrogen (ER) receptors, and human epidermal growth factor receptor-2 (HER-2) are systematically assessed and applied in clinical practice (3). However, all these traditional biomarkers have suboptimal effects on the treatment of BC, since the disease is caused by the accumulation of multiple molecular alterations (4). C35 is a newly identified biomarker of BC, also termed C17orf37, is located within the minus region of human chromosome 17q12 bounded by the oncogene ERBB2 and the growth factor receptor-bound protein 7 (GRB7) genes, and encodes a 12kDa membrane-anchored protein (5). By comparing 10 kinds of human mammary carcinoma cell lines and 38 kinds of normal tissue cells, Evans et al. reported that C35 was highly expressed in 7 kinds of carcinoma cell lines but barely expressed in normal cells except for Leydig cells (5). Overexpression of C35 was also detected in other cancer cells and tissues.
and metastasis (7, 8). These studies suggested that C35 functions as an oncogene and highlight biomarker in breast cancer cell lines and has a potential application value in BC therapies. In this study, the extensive detection of C35 protein expression in 68 breast cancer tissues and 20 normal tissues was executed to investigate the clinicopathologic correlation, including differences of tumor types and age groups. The expression of C35 was also compared with the expression of the hormone receptor ER, PR and HER-2, in order to demonstrate the expression relationships among the genes; in addition, analysis of C35 expression pattern in different BC molecular subtypes was also evaluated.

2. Materials and Methods

2.1. Source of samples

Cancer tissue samples and normal breast tissues were collected from the Second People's Hospital of Jining City in Shandong Province with the informed consent of patients, and were excised between July 2012 and January 2015. All of the 68 cancer samples were obtained from female inpatients and ranged in age from 34 to 81 years, with a mean and median age of 49 years. Normal tissue samples were derived from 20 cases of hyperplasia of mammary gland patients and mammary gland fibroma excision patients. Female patient age range was 17 to 38 years, with a median and mean age of 26.67 years. All of these samples were subjected to immunohistochemistry.

2.2. Clinicopathologic characteristics of patients

Inpatients involved in this study included 45 premenopausal patients and 23 postmenopausal patients. Samples ranged in degree of lymph node involvement, and included 43 axillary lymph node metastasis cases and 25 no metastasis cases. Of all the samples, 43 were invasive ductal carcinoma (IDC), 17 were invasive lobular carcinoma (ILC) and 8 were other carcinomas. Diameter of tumors ranged from 2.0 to 6.0 cm, 19 cases were less than 2 cm, 35 cases were 2~5cm and 14 cases were greater than 5 cm.

According to the clinical Tumor Node Metastasis (TNM) staging and confirmed by two qualified pathologists individually, samples were staged as 12 cases of stage I, 32 cases of stage II and 24 cases of stage III to IV. Samples were graded according to a modified Scarff-Bloom-Richardson (SBR) system by Elston Ellis, of which 14 were classified to Grade I (low malignant), 41 were classified to Grade II (moderate malignant), 13 were Grade III (highly malignant).

2.3. Sample selection criteria

Samples were selected according to four criteria: 1) Have complete clinical and pathological records; 2) All samples have been confirmed to be the primary breast cancer after surgery; 3) None of the patients received preoperative treatment such as neoadjuvant chemotherapy, endocrinotherapy and radiotherapy; 4) Surgical procedures included radical mastectomy, modified radical mastectomy and breast-conserving therapy plus axillary lymph node dissection. The study protocol was approved by the Hospital Ethics Review Committee.

Samples were excluded according to the following two criteria: 1) Abandon bilateral primary breast cancer cases and complicated patients with other malignant tumor; 2) According to National Comprehensive Cancer Network (NCCN) guidelines, abandon patients who have been undergoing postoperative treatment such as chemotherapy, radiotherapy and endocrine therapy in terms of their tumor stage and hormone receptor level.

2.4. Immunohistochemistry

Samples were fixed with 10% paraformaldehyde and made into 4 μm paraffin embedded serial sections. Immunohistochemical streptavidin-biotin complex (SABC) staining was performed according to the instruction of SABC immunohistochemical detection kit (Boster Biological Technology, Wuhan, China) at 1:100 dilution and rabbit anti-ER, PR and HER-2 monoclonal antibodies (Boster, Wuhan, China) at 1:20 dilution were used in this study.

ER and PR tumors were defined as positive only when the brownish yellow granules appeared in the cell membrane. A final manual immunohistochemistry grade was devised by adding the staining score and positive proportion score together. The staining scores were evaluated according to the staining intensity as follows: 0 for unstained cells, 1 for cells stained pale yellow, 2 for cells stained brownish yellow, 3 for cells stained brown. Scores of 0 were considered negative, scores of 1 were considered weakly positive, scores of 2 were considered moderately positive, and scores of 3 were considered strongly positive. The positive proportion of stained cells was calculated according to semi-ration standard using cell counting estimation, and the method was as follows: first the highest intensity of tissue staining was found at low magnification, then a total of 100 cells were counted under five high power fields (HPF for 400×) to calculate the proportion of positive cells, and the positive proportion score was established on the basis of the following criteria: 1 for 0-10%, 2 for 10-25%, 3 for 26-50%, and 4 for > 50%
2.5. Statistical analysis

Statistical analysis was performed using the Statistical Package for the Social Sciences (SPSS) 18.0 (USA). A possible correlation between C35 expression and clinicopathological parameters was assessed using a chi-square ($\chi^2$) test or Fisher’s exact test. Differences with a p value less than 0.05 were considered to be statistically significant.

3. Results

3.1. Expression of C35 protein in breast Carcinoma

The overexpression of C35 protein in human breast carcinoma specimens was detected by immunohistochemical SABC staining of 68 breast cancers and 20 normal breast tissues. Results indicated that expression of C35 was mainly localized at the plasma membrane of breast cancer cells, with profiles of brown or brownish yellow granules, as shown in Figure 1A. At the same time, no positive staining existed in mesenchymal cells. For normal breast epithelium tissue, in contrast, only a minimal number of cells showed weakly positive staining, as shown in Figure 1B. Positive immunohistological grades of HER-2 cells was assessed by the following standard: (−) for negative or nonspecific staining; (+) for > 10% discontinuous membrane coloration; (++) for > 10% with moderate intensity of membrane coloration consecutively; (+++) for > 10% with strong intensity of membrane coloration consecutively.

(A) Breast carcinomas tissues stained intensely with a brownish yellow granules pattern for strong positivity of C35. (B) Negative expression of C35 in normal breast tissues. Magnification, ×100.
groups ($\chi^2 = 31.731, p < 0.01$).

### 3.2. Correlations between C35 expression and clinicopathological parameters

As the positive C35 staining results show in Table 1, C35 expression increases with tumor TNM stage and SBR grade progression. The expression of C35 among different clinical stages ($\chi^2 = 16.608, p < 0.01$) was significantly different, as well as in different histopathological grades ($\chi^2 = 14.947, p < 0.01$). In addition, increasing C35 was more prevalent among BC patients with regional armpit lymph node metastasis (90.7%) than in BC patients without lymph node metastasis (68.0%) ($\chi^2 = 4.151, p < 0.05$). However, a similar expression frequency of C35 was detected both in IDC and ILC, with no statistically significant difference ($\chi^2 = 4.485, p = 0.106$). Similarly, there was no significant association between C35 expression and other clinicopathological parameters such as age, menstrual status, and tumor diameter ($p > 0.05$).

### 3.3. Expression of ER, PR and HER-2 in Breast Carcinoma

Expression of ER, PR and HER-2 detected by SABC staining are shown as Figure 2. The positive rate of ER, PR, and HER-2 were 45.59% (31/68), 41.18% (28/68), and 63.24% (43/68) of total BC specimens respectively. Expression of ER, PR, and HER-2 were analogously detected.

associated with tumor SBR grade, TNM stage and lymph node metastasis, with a significant difference ($p < 0.05$) respectively. The increasing positive rate of HER-2 also can be seen in the advanced TNM stage and SBR grade, as well as in larger size of tumors ($p < 0.05$). When compared with different pathological types of BC, however, the expression of HER-2 was concordant in IDC and ILC ($p > 0.05$) whereas a significant difference was observed in ER parcelling tests ($p < 0.05$). Likewise, the expression of those three biomarkers show also no significant difference with patients age and menstrual status ($p > 0.05$), as shown in Table 2.

3.4. Relationships between expression of C35 and other biomarkers

Table 3 shows the relationships between expression of C35 and the other three biomarkers ER, PR and HER-2. Correlation analysis showed that the expression of C35 in BC samples has a positive correlation to the expression of HER-2 ($\gamma = 0.207$), whereas has negative correlations to the expressions of hormone receptors ER ($\gamma = -0.035$) and PR ($\gamma = -0.083$).

3.5. Relationships between C35 expression and molecular subtypes of breast carcinoma

To detect relationships between C35 and BC molecular subtypes, all of the 68 samples were divided into four main subtypes by immunohistochemistry (9). The molecular subtype criterion were as follows: 1) Luminal A subtype: HER-2 negative but ER and/or PR positive (HER-2−/ER+/PR− or HER-2−/PR+); 2) Luminal B subtype: HER-2 positive, ER and/or PR positive (HER-2+/ER+/PR+ or HER-2+/ER+/PR− or HER-2+/ER−/PR−); 3) Basal-like subtype: ER, PR and HER-2 all negative (HER-2−/ER−/PR−); 4) HER-2 subtype: only HER-2 positive (HER-2+/ER−/PR−). Table 4 shows that there was no significant difference between multiple molecular subtypes of BC and C35 positive expression according to chi square test result ($\chi^2 = 2.922$, $p > 0.05$).

4. Discussion

Recently, molecular biomarkers have been introduced to overcome the inherent subjectivity of BC involved in histopathology, such as ER, PR and HER-2 (10), and therapists tend to formulate a pointed therapeutic plan on the basis of biomarker expression results. Slamon et al. (11) reported that HER-2 protein overexpression can merely be detected in 13-20% of IDC patient tissues, and the expression levels rise with the increase of tumor clinical stage and histological grade. Moreover, overexpression of HER-2 was associated with improved clinical outcomes (12). Clinical trials have demonstrated that patients with HER-2 (+) BC could achieve a satisfactory therapeutic effect by using a humanized monoclonal antibody against HER-2 (trastuzumab) (13). However, the proportion of HER-2 protein overexpression patients is only 20-40% (11), which limited the clinical use of trastuzumab in the majority of patients without HER-2+ BC. At the same time, the cytotoxicity of trastuzumab on the heart narrows the pool of candidates eligible for HER2-directed therapies (13,14).

TAM has been established as one of the most effective drugs in estrogen receptor-dependent BC treatment, and has been widely used as the first-line of anti-tumor drugs. Nevertheless, recent findings have shown that the frequent occurrence of drug resistance against TAM substantially reduced its anti-tumor efficacy, and the resistance mechanism of TAM remains unclear (15).

Consistent with previous study (5), our results demonstrated that a high level of C35 protein was frequently expressed in BC cells and tissues compared to normal breast cells, and the expression intensity difference was up to 10 times greater, thus it became a new attractive BC biomarker. In this study, the positive rate of C35 protein (82.35%) is higher than the other three biomarkers ER, PR and HER-2 at all stages. Increased expression level of C35 during tumor progression was also detected when correlating with SBR grade and TNM stage. Simultaneously, our results indicated that durative expression of C35 was associated with the clinical and pathological features of BC, since a higher positive rate was found in lymph node metastatic tumor tissues. Our results suggested that C35 expression might play an important role in tumor progression and lymphatic metastasis, in agreement with the conclusion presented previously.
(7,16,17). Although these features were not independent prognostic factors, they were also associated with poor clinical outcome. At the same time, Dasgupta S et al. also indicated that down regulation of C35 results in reduced expression of MMP-9, uPA and VEGF in prostate cancer cells (7), which have been reported to be positively correlated with poor prognosis (18). Therefore C35 shows potential as a prognostic indicator for BC. In combination with previous results, C35 is involved in cancer cell migration and metastasis by prenylation of its C-terminal CAAX motif (16), has a functional role in prostate cancer infiltration (7) and drug resistance of ovarian (17) cancer, and hence might be a more appropriate and reliable biomarker for tumor diagnosis and prognosis, and is also likely to be a new therapeutic target for cancer treatment.

Our results found that C35 expression was independent of age and menstrual status of patients, but needs further evidence from similar research work using a larger panel of patients. In the present study, the positive rate of C35 expression was significantly higher than previous work (5), these differences might be related to clinicopathological factors. A majority of samples in this work occurred in advanced histological grade and clinical stage, or in BC with lymph node metastasis, which may attribute to a higher score for C35 expression.

Based on the previous study (5), C35 was strongly associated with the expression of HER-2 protein and inversely associated with clinical pathological features of BC such as pathological grade, clinical stage and lymphatic metastasis, and the frequency of C35 was higher than HER-2 at all stages (14), which was consistent with our results. At the same time, the correlation between C35 expression and four BC molecular subtypes was irrelevant (p > 0.05) in this study, and the expression of C35 highly overlapped the other three biomarkers, which indicated that C35 was prevalent in all those BC molecular subtypes.

In conclusion, our findings indicate that high frequency of C35 expression could occur in all stages of BC, has a significant correlation with the clinicopathological factors including disease progression and lymphatic metastasis, and is also positively related to traditional biomarker HER-2, suggesting C35 has a great potential to be a reliable diagnostic marker, or to develop a new C35-targeted therapy in the clinical treatment of BC.

Summary The present study examined whether miR-17, miR-21, miR-29a, and miR-92 that are dysregulated in colon cancer (CC) can serve as potential predictive markers for relapse of disease after radical surgery and adjuvant chemotherapy. Real-time reverse transcription quantitative polymerase chain reaction was used to measure the expression levels of the miRNAs in serum samples from 37 patients with CC and 7 healthy individuals, tested as a control group. The area under the receiver operating characteristic curve (AUC) was then used to evaluate the predictive performance of the four miRNAs alone or in combination and compare it with carcinoembryonic antigen. The expression of miR-17, miR-21 and miR-92 were significantly higher in serum of patients with disease relapse. The AUCs for miR-17, miR-21, miR-92 for Nx patients were 0.844, 0.948, and 0.935, respectively (p < 0.05). Combining the four miRNAs for stage III patients increased the diagnostic performance, yielding an AUC of 0.881, with a sensitivity of 83.3% and a specificity of 85.7% (p < 0.05). Our study suggests that the expression levels of serum miR-21, miR-17, and miR-92 in patients with CC who underwent radical surgery and adjuvant chemotherapy may have diagnostic value for differentiating between recurred and non-recurred patients.

Keywords: miRNA, marker, relapse, Nx

1. Introduction

Colorectal cancer (CRC) is the most commonly diagnosed gastrointestinal cancer worldwide with more than 1.2 million new cases and 600,000 deaths annually (1). Oncological management of colon cancer patients is based on the initial clinical staging of the disease. For patients without metastatic disease (M0), surgery is the first option, used with curative intention. Unfortunately, for 20-30% of the patients the prognosis is poor due to recurrence of the disease (2). 5 Fluorouracil (5-FU) based chemotherapy is the standard adjuvant treatment. In stage III patients, the benefit from additional adjuvant chemotherapy is confirmed in several large-scale trials and they have about 40% lower risk of recurrence, compared to patients who were stated on observation (3,4). In stage II patients, adjuvant treatment remains controversial (5,6). Survival rate is usually complicated by the side effects of chemotherapy. This is mainly ascribed to the lack of reliable markers that could predict development of disease relapse. Therefore, identification of such markers would be greatly beneficial for the individualized chemotherapy of patients with a high risk for recurrence of the disease.

Disease relapses after surgery alone or combined
with adjuvant treatment for colon cancer are a function of both degree of bowel wall penetration of the primary lesion and nodal status (7). Nx category includes patients with unknown nodal status. Last Surveillance, Epidemiology, and End Results (SEER) population-based colon cancer analysis includes 130,762 patients with colon cancer, among which 14% (n = 18,312) were defined as Nx (7). Despite the large number of Nx cases, the potential benefit of chemotherapy is not known (8) and there are only a few biomarkers that could predict recurrence of the disease in this group of patients (9).

miRNAs are a class of short (18-23 nucleotides in length), endogenous, non-protein-coding RNAs that play critical roles in diverse biological processes through negative post-transcriptional regulation (10,11). miRNAs can function as oncogenes or tumor suppressors by repressing cancer-related genes (11,12). Alterations of miRNA expression have been observed in a variety of human tumors, including colon cancer, and it was discovered that miRNAs are stably present in circulating blood at sufficient levels for use as blood-based biomarkers (13,14). Thus, identification of novel serum-based miRNAs as biomarkers for response to therapy or tumor recurrence could improve the outcome of the disease.

In this study, we investigated the serum levels of four miRNAs involved in tumor cell proliferation (miR-17, miR-92), survival (miR-21), and metastasis (miR-29a) in colon cancer patients (15). Blood samples were collected immediately after completion of adjuvant chemotherapy. We aimed to monitor the tumor biological behavior and the prediction capacity of the serum levels of miR 17, miR-92, miR-21 and miR-29a for recurrence of the disease in one year period.

2. Materials and Methods

2.1. Ethics statement

All procedures were approved by the Scientific Research Ethics Committee of Medical University "Prof. Dr. Paraskev Stoyanov", Varna. Blood samples were collected from 37 colon cancer patients and 7 healthy volunteers at the Medical Oncology Clinic, University Hospital "St. Marina", Varna after obtaining informed consent form (ICF) from all study participants. All patients with indications for adjuvant chemotherapy were discussed for participation in our trial and only subjects who agreed to participate and signed ICF were included.

2.2. Patient selection

All subjects in the study were of Caucasian race. Controls were matched to colon cancer patients by age. The characteristics of patients and controls are represented in Table 1. We included patients with colon cancer stage II (n = 6) and III (n = 13) as per American Joint Committee on Cancer (AJCC) Cancer Staging Manual, 7th ed., who have undergone radical surgery in our hospital; there was no residual disease or compromised edges post-surgery and patients have completed 5-FU based adjuvant chemotherapy. 18 patients had Nx lymph node status because the involvement of lymph nodes could not be determined (less than 12 lymph nodes examined). We obtained serum after last cycle of adjuvant chemotherapy and patients started follow-up regularly (every 3 months) with computed tomography (CT) or positron emission tomography PET-CT until progression for 1 year of follow-up.

2.3. RNA isolation and real-time PCR

Total RNA was extracted from 200 μL serum, using the miRNeasy mini kit (Qiagen) following the manufacturer's instructions. 5.6 × 10^5 copies cel-miR-39 synthetic RNA per sample were used as spike-in control (Qiagen). The RNA was eluted in 14 μL nuclease-free water supplied with the kit. Small RNAs were reverse transcribed with miScript II RT kit (Qiagen), using 5 μL of the eluted RNA and HiSpec buffer. Before use, cDNA was diluted as recommended. Quantitative real-time PCR was done on the StepOne
levels of miRNA were normalized to cel-miR-39 and quantity to a single reference sample (as a reference target and were expressed as relative quantities (RQ) of target miRNAs were calculated using PCR kit and miScript Primer Assays (Qiagen). Relative levels of miRNA were normalized to cel-miR-39 and were calculated using the equation $2^{-\Delta\Delta C_{t}}$. RQ values for miRNA-17, miRNA-21, miRNA-29a or miRNA-92 were then normalized to the average expression of each of these miRNAs in healthy individual (17). Greater than the median RQ values of miRNAs we denoted as high expression levels, and values below or equal to the median RQ we denoted as low expression levels.

2.4. Clinical and pathological features

We collected demographical data (sex and age at initial staging), date and extent of surgery, as well as tumor characteristics: localization, TNM classification, histology of tumor, total number of histologically examined lymph nodes, and grade of differentiation. Associations of serum miR-17, miR-21, miR-29a, and miR-92 expression with clinicopathological parameters are represented in Table S1 (http://www.biosciencetrends.com/docindex.php?year=2015&kanno=6).

2.5. Statistical analysis

Statistical analysis was carried out with SPSS Statistics v.23 using descriptive statistics. Categorical features were summarized with frequencies and percentages. The Mann-Whitney U test, Pearson correlation, and $\chi^{2}$ test or Fisher's exact test were used for comparison and estimation of correlations between miRNAs expression levels and clinicopathological characteristics such as tumor stage and grade, and age. Specificity and sensitivity of serum miRNAs expression levels for discriminating patients with recurrent disease (recurred patients, RP) from patients with non-recurrent disease (non-recurred patients, NP) at 1 year of follow-up were evaluated with receiver operating curve (ROC) analysis. Diagnostic accuracy of biomarkers was also determined by obtaining the largest possible area under the curve (AUC) in ROC analysis. The best linear combination of miRNA markers in the sense that the area under the ROC curve of this combination is maximized among all possible linear combinations was calculated according to the method of Su and Liu (18). Kaplan-Meier survival curves and the log-rank test were used to compare the survival differences between groups. Although our study was not powered enough to compare different subgroups, hazard ratios (HRs) and corresponding 95% confidence intervals (CIs) were calculated by Cox regression models. Two-tailed p-values (< 0.05) were considered as significant.

3. Results

3.1. Expression of miRNAs in NP, RP and control groups

Relative miRNA expression levels in serum samples of colon cancer patients (n = 37) who underwent curative surgery were obtained by using cel-miR-39 as reference genes for normalization. Relative quantification (RQ) values, calculated by the $2^{-\Delta\Delta C_{t}}$ method were used for evaluation of expression in patients. The Mann-Whitney test showed that there were no significant differences of RQ values of all 4 miRNAs between the control and NP group. Both miR-21 and miR-92 showed significant expression level differences between RP group with control and NP group (Figures 1B and 1D). In contrast, miR-17 showed significant difference only between RP group and NP group, but not between RP group and control group (Figure 1A). Expression level of miR-29a did not differ between groups (Figure 1C).

3.2. Expression of miR-21 differs between and within stages

There were no significant differences of RQ values of all miRNAs in patients with stage II, stage III and Nx except for miR-21, which differed between patients with stage II and III (Figure 2). Within stage III patients, none of the 4 miRNAs expression levels were different between RP and NP groups. However, within the Nx patients all miRNAs except miR-29a had significant differences in expression levels between RP vs. NP groups (Figures 3A, 3B and 3D).

3.3. miR-21, miR-17 and miR-92 alone discriminate RP and NP groups

After 1 year follow-up post adjuvant chemotherapy none of patients with stage II disease experienced recurrence. Six patients with stage III disease and 7 patients with Nx experienced recurrence after 1 year of follow-up. ROC analysis was performed to explore the potential value of analyzed miRNAs expression levels as noninvasive diagnostic biomarkers for recurrence after adjuvant chemotherapy (Figure 4). miR-21 allowed most accurate discrimination (AUC = 0.901, 95% CI: 0.788-1, p < 0.001) between RP and NP groups. At the optimal cutoff values of RQ, the sensitivity was 84.6% and specificity was 79.2% (Figure 4B). miR-92 and miR-17 could also discriminate RP and NP groups with the following AUC = 0.885 (95% CI: 0.778-0.991, p < 0.001) and with 84.6% sensitivity and 70.8% specificity (Figure 4D) and AUC = 0.814 (95% CI: 0.658-0.971, p = 0.002) and with 84.6% sensitivity.
and 66.7% specificity (Figure 4A) at the optimal cutoff values of RQ, respectively. miR-29a discriminates RP and NP groups with the following AUC = 0.670 (95% CI: 0.493-0.846, p = 0.092) and with 53.8% sensitivity and 70.8% specificity at the optimal cutoff values of RQ, but the result did not reach statistical significance (Figure 4C). For comparison, carcinoembryonic antigen (CEA) after adjuvant chemotherapy has lower power to discriminate RP and NP groups AUC= 0.655 (95% CI: 0.472-0.839, p = 0.123) with 61.5% sensitivity and 62.5% specificity, but the result did not reach statistical significance (Figure 4E).

3.4. miR-21, miR-17 and miR-92 alone or in combination discriminate RP and NP groups within stage III and Nx patients

The potential value of analyzed miRNAs as biomarkers for recurrence after adjuvant chemotherapy within stage III and Nx patients is shown in Table 2. Because none of the studied biomarkers could discriminate accurately in stage III between RP and NP groups, we constructed multimarker ROC analysis. The combination of all 4 biomarkers discriminates RP and NP groups with the following AUC = 0.881 (95% CI: 0.655-1, p = 0.022) and with 83.3% sensitivity and 85.7% specificity at the optimal cutoff values of RQ (Figure 4F). In patients with Nx disease only expression levels of miR-29a were not good enough to discriminate between patients with recurrence and no recurrence of the disease (Table 2). CEA after adjuvant chemotherapy has similar power to discriminate recurrence in stage III and Nx patients (Table 2).

3.5. No correlation of miRNA expression levels with disease free survival, age and CEA

www.biosciencetrends.com
Figure 3. Box plots, representing serum miRNAs expression levels in Nx group in RP (recurred patients) and NP (non-recurred patients). Expression levels of miRNAs (scale of y axis: ln). The Mann-Whitney test was used to detect significant differences of RQ (relative quantities) values of all 4 miRNAs between NP and RP group. Two-tailed p-values (< 0.05) were considered as significant. A, miR-17; B, miR-21; C, miR-29a; D, miR-92.

Figure 4. Receiver operating curve (ROC) curve analysis, using four miRNAs and CEA (carcinoembryonic antigen) to differentiate RP (recurred patients) from NP (non-recurred patients). Diagnostic accuracy of biomarkers was determined by obtaining the largest possible area under the curve (AUC) in ROC analysis. A, miR-17; B, miR-21; C, miR-29a; D, miR-92; E, CEA; F, Multimarker ROC analysis, using four miRNAs in stage III patients.
Disease free survival (DFS) was calculated as the time from the date of surgery to the date of documented recurrence of the disease. Colon cancer patients with high expression levels of any miRNAs had no significant differences in DFS compared with those with low expression levels of miRNAs (Figure S1, http://www.biosciencetrends.com/docindex.php?year=2015&kanno=6). In univariate analysis, older age, stage of disease, sex, histologic grade and expression levels of miRNAs were not associated with poor 1 year DFS (Table S2, http://www.biosciencetrends.com/docindex.php?year=2015&kanno=6).

Pearson correlation tests did not detect significant correlation between the DFS and the serum levels of the miRNAs studied. We also did not observe correlation between age and expression levels of the studied miRNAs. Furthermore, none of the 4 miRNAs correlated with serum level of CEA after adjuvant chemotherapy. However, strong correlation was observed between miR-17 and miR-92 ($r = 0.971, p < 0.001$, Figure S2), moderate correlation between miR-21 and miR-92 ($r = 0.492, p = 0.002$, Figure S2, http://www.biosciencetrends.com/docindex.php?year=2015&kanno=6) and weak correlation between miR-17 and miR-21 ($r = 0.360, p = 0.029$, Figure S2).

### 4. Discussion

Previous studies have identified multiple circulating miRNAs that are differently expressed and dysregulated in colon cancer patients compared with control healthy people (11,19,20). Several lines of evidence have suggested that miRNAs might serve as potential biomarkers for the diagnosis and prognosis of patients with colon cancer (19,21-23).

The goal of our study was to identify potential biomarkers that could predict early recurrence after adjuvant treatment. Additionally we included in our analysis patients with unknown lymph node status (Nx patients). Usually dysregulated miRNAs are associated with wide variety of cancers (24). To increase the sensitivity and specificity of our assay we used miR-21, miR-17, miR-29a and miR-92 which have been shown to be upregulated in colon cancer patients (25).

ROC analysis in our study showed that upregulation of any of miR-21, miR-92 and miR-17 in serum is an accurate biomarker and can distinguish colon cancer patients with recurrence from patients without recurrence with high sensitivity and specificity (Figure 4). In stage III patients, only the combination of all miRNAs reached statistically significant result in distinguishing RP from NP, which might be as a result of the small sample size. All miRNAs except miR-29a outperformed CEA serum levels in predicting recurrence. The sensitivity and specificity of ROC curve for prediction of recurrence on the basis of CEA only was low, which is consistent with other research (26).

Only a few studies have evaluated the expression levels of miRNAs after curative surgical resection of the primary tumor (21,27,28) and have looked for a diagnostic correlation between serum levels of miRNAs and post-adjuvant levels of CEA. In the present study the expression levels and the diagnostic significance of 4 circulating miRNAs (miR-17, miR-21, miR-29a and miR-92) from blood samples of colon cancer patients, who underwent radical surgery of the primary tumor and adjuvant chemotherapy were correlated with the serum levels of CEA (measured after end of adjuvant chemotherapy) and the stage of the disease.

Previous studies have found higher levels of circulating miR-17, miR-21, miR-29a and miR-92 as compared to healthy individuals and some of those miRNAs were associated with poor survival, independent of other clinicopathological factors (28-31). Among the most important target genes of miR-17 and miR-92 are the E2F family of transcription factors (Figure 5) that drive the progression from the G1 into the S phase of the cell cycle (15). Thus, increased levels of miR-17 and miR-92 promote tumor cell proliferation. Crucial target of miR-21 is PTEN (phosphatidylinositol-3,4,5-trisphosphate 3-phosphatase) which negatively regulates the PI3K (phosphatidylinositol-4,5-bisphosphate 3-kinase) pathway (15). As a result, increased level of miR-21 promotes tumor cell survival (Figure 5). In one study it was shown that the serum levels of miR-21 statistically

</table>
significantly plummeted after surgery in the subset of patients with potentially curative surgeries (21). Others demonstrated that stromal miR-21 expression was related to the expression of E-cadherin and metastasis-associated protein 1 in colorectal cancer and high miR-21 expression in stage III patients was not associated with poor DFS (32). Stage II colorectal cancer patients with high levels of miR-21 are at higher risk for tumor recurrence and should be considered for more intensive treatment (32). We found from our panel of miRNAs that only miR-21 had significantly altered expression levels in patients with III vs. II stage disease, which may reflect the tumor burden or may indicate noncurative surgeries. Patients with recurrence of the disease had significantly higher expression levels in Nx group for all miRNAs except miR-29a which again may reflect the tumor burden or may indicate noncurative surgeries.

There is considerable sample-to-sample variability in both protein and lipid content of serum samples, which could affect efficiency of RNA extraction (33). To ensure the accuracy of our assay, including variability in polymerase chain reaction amplification efficiencies, we used the novel method for normalization of experimental miRNA data using spiked-in synthetic, nonhuman mature miRNA from Caenorhabditis elegans (33). Although our approach of quantifying relative expression of serum miRNAs is widely used, absolute quantitation of serum miRNAs expression levels may further improve the translation of these data into a clinically viable diagnostic test for early detection of disease relapse.

Inadequate examination of lymph nodes may lead to tumor understaging and subsequent treatment failure (34). Many factors affect the number of lymph nodes examined, including extent of surgical resection, patient age, tumor location, and pathology techniques. Population-based data suggest that only 37% of colon cancer patients have adequate lymph node evaluation (35). Colon cancer patients may benefit from discovering prognostic markers that can identify those individuals that are more likely to recur by selecting patients that are suitable for adjuvant therapy. Several miRNAs (miR-192, miR-215, miR-140, miR-129, let-7, miR-21, miR-181b, miR-200 s) were found to be associated with chemo-resistance by regulating key cell death pathways (24). High levels of miR-21 may partly be responsible for poor response to 5-FU; therefore, patients with high miR-21 expression are at high-risk for disease recurrence (36). In colon cancer cell lines it was demonstrated that increased miR-21 expression reduced apoptosis and G2/M arrest.
M arrest due to damage by 5-FU (37).

In summary, the most important finding in our study is that miR-17, miR-21 and miR-92 alone in Nx or in combination in stage III patients may help detecting early recurrence of colon cancer after radical surgery and adjuvant chemotherapy with high accuracy in clinical practice. Our results suggest that patients with elevated serum levels of miR-17, miR-21 and miR-92 should undergo more intensive follow-up in order to increase the possibility for early relapse detection and potential subsequent curative interventions. To our knowledge our study, despite its small sample size, is one of the few, testing potential biomarkers that could predict disease recurrence in patients with Nx colon cancer. Future studies may further evaluate the potential use of miR-17, miR-21 and miR-92 in post-operative surveillance, which may provide an opportunity for early detection of recurrent disease.

Pancreatic adenocarcinoma: the impact of preneoplastic lesion pattern on survival

Yves Flattet¹, Takamune Yamaguchi², Snezana Andrejevic-Blant¹, Nermin Halkic²,*

¹Department of Pathology, University Hospital CHUV, Lausanne, Switzerland; ²Department of Visceral Surgery, University Hospital CHUV, Lausanne, Switzerland.

Summary
Pancreatic adenocarcinoma is associated with a very poor prognosis, characterized with a 5-year survival rate of only 5%. Surgery is the only curative treatment for selected patients. Nevertheless, recurrence is very frequent. Identifying prognostic factors is thus warranted. Like numerous other tumors, adenocarcinomas are preceded by preneoplastic lesions. The role and the impact of these lesions remain unclear. This study aimed to assess the impact of the preneoplastic lesion pattern and histomorphological features, on survival after pancreatic resection. Thirty-five patients who underwent pancreatic resection for pancreatic adenocarcinoma were identified from a prospective database of a single center, between 2003 and 2008. We considered demographics, tumor characteristics, and type of treatment. The major outcome was survival. Analyzes were separated into two groups, according to the preneoplastic lesions: Pancreatic intraepithelial neoplasia (PanIN)-related carcinomas and intracanalicular papillary mucinous neoplasia (IPMN)-related carcinomas. The former were more frequent, accounting for 63% (22/35). Moreover, they displayed more aggressive features, with a higher tumor stage \(p = 0.01\) and higher rate of positive lymph nodes \(p = 0.019\). Lymphatic \(p = 0.009\) and perinervous \(p = 0.019\) invasions were also more frequent. Survival was negatively influenced by PanIN preneoplastic lesions \(p = 0.015\), T3-4 tumor stage \(p = 0.038\), positive lymph nodes \(p = 0.044\), lymphatic \(p = 0.019\) and vascular \(p = 0.029\) invasions. Pancreatic adenocarcinoma displays different behavior according to its preneoplastic lesion. Indeed, PanIN-related adenocarcinoma showed more aggressive features and lower survival rate. Preneoplastic lesions may represent predictive factors for survival. Their role and predictive value should be investigated more thoroughly.

Keywords: PanIN, IPMN, pancreatic resection

1. Introduction
Pancreatic adenocarcinoma represents the fourth leading cause of death by cancer, worldwide (1). Its aggressive pattern is partially due to the silent course of the disease, with symptoms like jaundice or weight loss occurring late (1). Although surgery may be curative for early stages (2), overall recurrence rate is high while 5-year survival rate only reaches 5% (3). Significant advances have been made in the understanding of the biology and mechanisms of pancreatic cancer, during the last decade. Adenocarcinoma of the pancreas seems to result from successive mutations. A continuum of lesions may be observed between normal parenchyma and adenocarcinoma (4-7). The most frequent preneoplastic lesions that usually precede pancreatic adenocarcinoma are subdivided into two types: pancreatic intraepithelial neoplasia (PanINs) and intracanalicular papillary mucinous neoplasia (IPMN) (8-11). The former is a peripheral lesion affecting small pancreatic ducts (< 5mm in diameter), which is often described, in ductal adenocarcinoma. IPMN are less frequent lesions, usually occurring in the main pancreatic duct or its principle branches (11). Characterized by a size greater than 5 mm, they are more likely to be visible on imaging, compared to PanIN. As with PanIN, IPMN appear to follow an adenoma-carcinoma sequence with three continuous steps: low grade adenoma, borderline

neoplasia, and carcinoma in situ (12).

Both preneoplastic lesions, PanIN and IPMN, follow a sequence of events leading to adenocarcinoma. Notwithstanding, tumor progression may be different depending on the preneoplastic lesion (9). Studies have described the trend for PanINs leading into ductal adenocarcinoma, and for IPMN evolving toward mucinous adenocarcinoma. Although ductal- and mucinous adenocarcinomas obviously display different outcomes, the impact of various tumor characteristics, like the pattern of preneoplastic lesions remains unclear. In this study, we aimed to analyze the impact of histomorphological tumors’ characteristics on survival, in the setting of pancreatic resection for adenocarcinoma.

2. Materials and Methods

Thirty-five patients who underwent pancreatic resection for adenocarcinoma of the pancreas were identified from prospective databases for pancreas surgery, in the Division of Visceral Surgery at University Hospital of Lausanne (CHUV), between 2003 and 2008. A complete preoperative workup was performed to determine whether the disease was completely resectable and each case had been previously discussed in a tumor board. Surgical procedures were performed by conventional pancreatic resection including pancreaticoduodenectomy and distal splenopancreatectomy. Distal splenopancreatectomy was performed through exclusive abdominal incision or laparoscopic procedure. The artery-first approach was not performed in pancreaticoduodenectomy and reconstruction was done by pancreaticogastrostomy or pancreaticojejunostomy according to pancreas texture (13). Patients’ demographics, tumor characteristics, type of treatment and survival were analyzed. We considered: age, gender, type of surgery, histological type of tumor, preneoplastic lesion, TNM stage, tumor grade, lymphatic invasion, vascular invasion, neural invasion, margins status, adjuvant therapy and survival (DFS - disease free survival). Due to a limited number of patients, and in order to perform pertinent statistical analyzes, several classes of items were regrouped. Indeed, high grade tumors (G2 and G3) were grouped and compared to low grade tumors (G1), Tumor stages T1/2 were compared to T3/4 stages. The IPMN lesions were classified as low-grade (adenoma) and high grade (borderline neoplasia and carcinoma in situ). The margins status were separated into margins > 0.1cm and margins ≤ 0.1cm. Clinical follow-up was analyzed according to tumor-free survival, survival with disease, death without disease and death with disease.

The overall survival curves were determined using the Kaplan-Meier method and were compared using the log-rank test. A multivariate analysis was performed using a Cox proportional hazards model. A significant value of 0.05 was used in all tests. The statistical analysis was done using SPSS v20 statistical software, Chicago, IL.

3. Results

3.1. Patients and tumors

Patients’ characteristics are summarized in Table 1. Median age was 69 years while men accounted for 57% (20/35). Tumors were separated in two groups, based on the preneoplastic lesion (Table 1). A majority of tumors were related to PanIN 63% (22/35) while 13 adenocarcinomas (37%) were related to IPMN. Although, the 2 groups were comparable in regard to several characteristics, they were significantly different for the following variables: tumor stage ($p = 0.01$), lymph node ($p = 0.019$), lymphatic invasion ($p = 0.009$) and perineural invasion ($p = 0.019$). Moreover, PanIN-related tumors more frequently required pancreaticoduodenectomy.

3.2. PanIN-related adenocarcinomas

They displayed aggressive features with 86% stage T3-4. Moreover, 73% had lymphatic metastasis. Distant metastasis accounted for 14% while a majority presented a high tumor grade G2-3 (86%). Vascular and perinervous invasion were highlighted in 46% and 91%, respectively. Treatment was mostly pancreaticoduodenectomy (91%) while pathological R0 resection was carried out in 46%. Furthermore, 64% of patients received adjuvant therapy.

3.3. IPMN-related adenocarcinomas

This subtype of tumors displayed less aggressive features than PanIN-related adenocarcinoma. However, we identified 39% as T3-4 stage, 31% with positive lymph nodes while distant metastasis concerned 15% (2/13). In term of invasion, tumors invaded vessels, lymphatics and nerves in 39%, 31% and 54%, respectively. Surgery was relatively well balanced between pancreaticoduodenectomy (61.5%) and distal splenopancreatectomy (38.5%). Pathological R0 resection was carried out in 54%, and half of the patients received an adjuvant treatment.

3.4. Survival

The impact on survival was analyzed for each variable and is described in Table 2. Demographics did not show a significant difference for survival rate. As mentioned above, PanIN-related adenocarcinomas displayed more aggressive features than IPMN-related ones. Indeed, these findings influenced survival with a significantly lower survival rate in the former group ($p = 0.015$, Figure 1). Lymph node metastasis was also identified...
pancreatic adenocarcinoma, on survival after pancreatic resection. Although, pancreatic adenocarcinoma may be classified according to their subtype: ductal vs. mucinous, the preneoplastic lesion pattern appeared to play an important role \((9)\). Indeed, PanIN-related tumors displayed more aggressive characteristics than IPMN-related ones. These findings were translated into survival with poorer prognosis in the PanIN-related group. The survival rate at 1-, 3- and 5-years were 69%, 58% and 58% for IPMN-related tumors while it only reached 45%, 19% and 9% for PanIN-related adenocarcinomas.

Tremendous effort has permitted a significant improvement in understanding tumorigenesis of pancreatic adenocarcinoma and precancerous lesions, during the last decade \((14-16)\). The pathological

</table>

as a prognostic factor and was associated with lower survival \((p = 0.038, \text{Figure 2})\).

The invasion of adjacent tissues by the tumor appeared to influence survival, via three mechanisms: direct invasion \((p = 0.038)\), vascular invasion \((p = 0.029)\) and lymphatic invasion \((p = 0.019)\), while perineurial invasion was not associated with poorer outcomes \((p = 0.119)\). None of the therapeutic variables influenced survival in our study. Multivariate analysis did not detect any significant impact on survival for the studied variables.

**4. Discussion**

This study assessed the impact of preneoplastic lesion pattern and histo-morphological features of pancreatic adenocarcinoma, on survival after pancreatic resection. Although, pancreatic adenocarcinoma may be classified according to their subtype: ductal vs. mucinous, the preneoplastic lesion pattern appeared to play an important role \((9)\). Indeed, PanIN-related tumors displayed more aggressive characteristics than IPMN-related ones. These findings were translated into survival with poorer prognosis in the PanIN-related group. The survival rate at 1-, 3- and 5-years were 69%, 58% and 58% for IPMN-related tumors while it only reached 45%, 19% and 9% for PanIN-related adenocarcinomas.

Tremendous effort has permitted a significant improvement in understanding tumorigenesis of pancreatic adenocarcinoma and precancerous lesions, during the last decade \((14-16)\). The pathological
characteristics and molecular mechanisms have rapidly evolved, leading to new classification of preneoplastic lesions (8). Notwithstanding, the relationship between these findings and the clinical setting is not obvious yet. This study displays some limitations. The retrospective design leads to missing data and missing variables. Moreover, the number of included patients is relatively low. Based on these potential biases, results should be interpreted with caution.

In a landmark article, Andea et al. showed the association between PanIN and ductal adenocarcinomas (9). Therefore, the need to address and treat these progressive lesions at an early stage is crucial. Of note, the influence of preneoplastic lesion pattern on survival after resection has rarely or not been addressed, to our knowledge. Based on our results, preneoplastic lesions may play an important role. At least, they may reflect different oncogenic pathways, according to their respective type. Pancreatic adenocarcinomas are heterogeneous tumors with poor prognosis while prognostic tools as biomarkers are somewhat lacking. Identifying subclasses is thus a critical step for the future.

The relatively small number of cases (n = 35) was a limitation of our study. This may be the reason why well-known risk factors, such as perineural invasion, were not associated with poorer outcomes. This result should be confirmed in a future study carried out in a larger cohort of patients.

In summary, this study supports the influence of preneoplastic lesions on survival, after pancreatic resection for adenocarcinoma. PanIN-related lesions displayed more aggressive features than IPMN-related ones, leading to a lower survival rate. Further studies are needed in order to explore the role of precancerous lesions of the pancreas, in more depth.

After resection has rarely or not been addressed, to our knowledge. Based on our results, preneoplastic lesions may play an important role. At least, they may reflect different oncogenic pathways, according to their respective type. Pancreatic adenocarcinomas are heterogeneous tumors with poor prognosis while prognostic tools as biomarkers are somewhat lacking. Identifying subclasses is thus a critical step for the future.

The relatively small number of cases (n = 35) was a limitation of our study. This may be the reason why well-known risk factors, such as perineural invasion, were not associated with poorer outcomes. This result should be confirmed in a future study carried out in a larger cohort of patients.

In summary, this study supports the influence of preneoplastic lesions on survival, after pancreatic resection for adenocarcinoma. PanIN-related lesions displayed more aggressive features than IPMN-related ones, leading to a lower survival rate. Further studies are needed in order to explore the role of precancerous lesions of the pancreas, in more depth.

Summary
Despite increasing popularity of single-incision laparoscopic cholecystectomy (SILC), indication criteria assuring safety of SILC has yet to be established. In the present study, the subjects consisted of 146 consecutive patients undergoing conventional laparoscopic cholecystectomy (CLC) or SILC. SILC was indicated after excluding patients who met following criteria: age > 75 years, obesity, operative scar, cardiopulmonary diseases, acute cholecystitis, choledocholithiasis and abnormal bile duct anatomy. Thirty-four patients were excluded from the SILC candidates (moderate/high-risk CLC group). Among the 112 potential candidates, SILC was indicated for 23 patients (21%, SILC group) and the remaining 89 patients (79%) underwent CLC (low-risk CLC group). In the SILC group, operation time was longer than in the low-risk CLC group (171 [113-286] vs. 126 [72-240] min, p < 0.01), but the periods requiring painkiller was shorter. That led to reduced length of hospital stay compared to low-risk CLC group (2 [2-4] vs. 4 [2-12] days, p < 0.01). Between the low-risk CLC and moderate/high-risk CLC group, operation time was significantly longer and amount of blood loss was larger in the latter group. No complications were encountered in the SILC group. SILC can be indicated safely as far as appropriate criteria is adopted for excluding patients in whom complicated laparoscopic procedures are needed.

Keywords: Conventional multiport laparoscopic cholecystectomy, fluorescence cholangiography, single-incision laparoscopic cholecystectomy

1. Introduction
Single-incision laparoscopic cholecystectomy (SILC), which was first introduced by Navarra et al. (1), is increasingly gaining popularity presumably because SILC has definite advantage in improving cosmesis after laparoscopic cholecystectomy (LC) (2,3). In some institutions favoring SILC over conventional multipor laparoscopic cholecystectomy (CLC), incidence of SILC reached 50% among all the LC procedures (4,5). In contrast, SILC has potential disadvantages compared to CLC in terms of longer operative time (6), increased cost for specialized laparoscopic instruments (7), a higher bile duct injury rate (8), and occurrence of umbilical hernia (3,9). In order to safely adopt SILC in clinical practice, we need strict criteria for indication of SILC, which have not been indicated clearly even in the guideline of LC by the Society of American Gastrointestinal and Endoscopic Surgeons (10).

In the authors’ institution, SILC has been performed after setting definite exclusion criteria comprising patients’ background factors and gallstones/cholecystitis conditions. The present study evaluated intra- and post-operative outcomes of SILC compared to those of CLC with the aim to consider appropriate criteria for indicating SILC safely to patients who opt for single-incision surgery.

2. Materials and Methods

2.1. Patients
The subjects consisted of 146 consecutive patients who underwent LC for cholecystolithiasis, gallbladder...
polyps, or acute cholecystitis at The University of Tokyo between December 2009 and April 2012. Exclusion criteria for SILC were determined as follows: age > 75 years, obesity (BMI > 30 kg/m²), operative scar in the upper abdomen, concomitant cardiopulmonary diseases, acute cholecystitis, choledocholithiasis, abnormal bile duct anatomy detected by routine preoperative cholangiography on computed tomography, magnetic resonance images, or fluoroscopy. These criteria were set to secure the safety based on the studies which indicated higher postoperative morbidity rate following CLC for patients with higher age (11), the higher grade in American Society of Anesthesiologists score (11), and complicated and/or acute gallstone disease (11-13). SILC was indicated for patients who met the criteria and opted for SILC after being presented explanation on the potential benefits and disadvantages of this procedure. CLC and SILC were performed or guided by surgeons who have experienced general surgery and LC for more than 10 years. All operations were performed after obtaining informed consent from each patient, and patient anonymity was preserved.

2.2. Surgical techniques

For CLC, patients were placed in the supine position under general anesthesia as well as epidural anesthesia. The trocar for laparoscopy was placed via the umbilical region, and 2 to 3 trocars were generally placed on the epigastric region and on the right side of the umbilicus. For SILC, on the other hand, patients were placed in the supine position with legs spread apart under general anesthesia with local anesthesia around the umbilicus. SILS port (Covidien, Mansfield, MA, USA) and a 5.4 mm-flexible laparoscope were used. A 2 mm visceral tractor (Mini Loop Retractor II; Covidien) was also used to lift the fundus of the gallbladder (14). The procedure was performed through Semi-cross method, holding an articulating instrument (Roticulator Endo Grasp; Covidien) with the left hand and a straight instrument with the right hand (15). The triangle of Calot was dissected to reach "critical view of safety" (16), while using fluorescence cholangiography (17-20) with preoperative and intravenous injection of ICG at any time during the procedures (Figure 1 and supplementary video 1, http://biosciencetrends.com/docindex.php?year=2015&kanno=6). When the isolation of the cystic duct was not completed within one hour after the incision, the second trocar was then placed to facilitate laparoscopic procedures. During this study period, intraoperative drip infusion cholangiography using meglumine iotroxate (21) (Figure 2) as well as fluorescence cholangiography was also routinely performed for both LC and SILC at the authors' institution. The cystic duct was ligated and divided after confirming the anatomy of the common bile duct using drip infusion cholangiography and fluorescence cholangiography, and consequently, the gallbladder was removed from the liver and retrieved. In principle, a drainage tube was not placed.

2.3. Postoperative management

The catheter for the epidural anesthesia in CLC was removed on postoperative day 2. Non steroid anti-inflammatory drug was administered intravenously or orally to relieve postoperative pain depending on patients' complaint. Patients were discharged from the hospital when levels of C-reactive protein and hepat
biliary enzyme in blood were confirmed to be within normal limit on PODs 1 and/or 3 and when they had recovered from impaired activities of daily living. Follow-up was conducted for at least 6 months after surgery.

2.4. Statistical analysis

The subjects were divided into the following three groups: patients who met the exclusion criteria for SILC and underwent CLC (moderate/high-risk CLC group), those who were potential candidates of SILC but underwent CLC (Low-risk CLC group), and those who were potential candidates of SILC and actually underwent SILC (SILC group). Background characteristics and postoperative outcomes were compared between the Low-risk CLC group and the SILC group. Intraoperative factors were compared among the low-risk CLC group, the moderately/high-risk CLC group, and the SILC group.

Categorical variables are expressed in numerical figures (%), and were compared between groups using Fisher's exact test or the chi-square test. Continuous variables were expressed as median values (with range), and were compared using the Wilcoxon's rank-sum test. In the analysis of intraoperative factors among the three groups, the Steel-Dwass test was used following Kruskal-Wallis test. $p$ values < 0.05 were considered as denoting statistical significance. Statistical analysis was conducted using JMP software (version 9.0.2; SAS Institute Inc., Cary, NC).

3. Results

3.1. Background characteristics

The treatment flow in the study population is shown in Figure 3. Among the 146 patients, 34 (23%) patients were excluded from the candidates of SILC (the moderate/high risk-CLC group) due to high age ($n = 13$), obesity ($n = 11$), acute cholecystitis ($n = 3$), surgical scar in the upper abdomen ($n = 2$), and abnormal bile duct anatomy on preoperative cholangiography ($n = 5$). Of the remaining 112 candidates of SILC, 23 (21%) patients opted for SILC and 89 patients (79%) underwent CLC. Between the 23 patients in the SILC group and the 89 patients in the low risk-CLC group, the former group included younger patients and larger ratio of female patients (Table 1).

3.2. Intraoperative outcomes

Intraoperative factors are summarized in Table 2. Operation time in the low-risk CLC group was significantly shorter than that in the SILC group (126 [72-240] min vs. 171 [113-286] min, $p < 0.01$) and also than that in the moderate/high-risk CLC group.

(126 [72-240] min vs. 150 [100-343] min, p < 0.023). Estimated blood loss in the low-risk CLC was similar to that in the SILC group but smaller than that in the moderate/high-risk CLC group (low-risk CLC 3 [0-100] mL vs. moderate/high-risk CLC 5 [0-250] mL, p = 0.017). In the SILC group, additional trocars were needed in 2 patients (9%), one patient with BMI 29.9 kg/m² and severe adhesion around the liver and the gallbladder and the other patient with severe inflammation around the hepatoduodenal ligament). No intraoperative complication was observed in the SILC group. Conversion to laparotomy was needed for one patient (1%) in the low-risk CLC group and one patient (4%) in the moderate/high-risk CLC group due to the diagnosis of gallbladder carcinoma in the intraoperative pathological findings.

3.3. Postoperative outcomes

Postoperative complications (Clavien-Dindo classification [22] grade II or more) developed only in the Low risk-CLC group (pleural effusion and intra-abdominal abscess, Table 3). No bile leak was encountered in the SILC group or in the Low risk-CLC group. Postoperative hospital stay was significantly shorter in the SILC group than in the Low risk-CLC group (2 [2-4] days vs. 4 [2-12] days, p < 0.01). Patients in the SILC group needed postoperative for shorter periods compared to those in the Low risk-CLC group (Table 3).

4. Discussion

In the present study, LC has been performed in 146 consecutive patients using the definite exclusion criteria for SILC. According to our criteria, 77% of the patients undergoing LC were defined as potential candidates for SILC, and of those, 23 patients decided to undergo SILC. In the SILC group, additional trocars were needed in two patients (9%) and no conversion to open surgery was required. Although operation time was significantly longer in the SILC group than in the low-risk CLC group, SILC led to better postoperative outcomes in terms of length of hospital stay and postoperative painkiller use most likely due to its less-invasiveness without increasing risk of operative complications compared to CLC. These results suggest that SILC can be applied safely to patients who prefer better cosmetic outcomes if appropriate indication criteria for SILC is established.

In the previous series, some authors have proposed exclusion criteria for SILC consisting of clinical factors such as BMI > 35 or 40 kg/m² (4,22,23), cholecystitis (4,22), abdominal scar (4,22,23), choledocholithiasis (4,23), pacemaker (22), and pregnancy (22) (Table 4). Since operation time of SILC tend to be longer than that in the CLC, it is reasonable to consider patients with a high risk of general anesthesia and clinical factors that can further prolong operation time as contraindications for SILC. Since operation time of SILC trend to be longer than that in the CLC, it is reasonable to consider patients with a high risk of general anesthesia and clinical factors that can further prolong operation time as contraindications for SILC. The long operation time in our series was most likely due to unskilled surgical skills for single incision technique in addition to the application of intraoperative ICG-fluorescence imaging. In the present series, on the other hand, we regarded patients as having moderate/high risk of LC and contraindication for SILC if they met any of the followings: higher age, obesity, operative scar in the upper abdomen, concomitant cardiopulmonary diseases, acute cholecystitis, choledocholithiasis, and abnormal bile duct anatomy. Indeed, operation time and estimated blood loss in the moderate/high-risk CLC group were unfavorable compared to those in the low-risk CLC group, suggesting that our criteria may serve to assure safety of SILC. In contrast, our indication criteria for SILC are stricter than those used in the previous series in terms of restrictions in age and BMI. In particular, routine use of preoperative cholangiographic images to evaluate bile duct anatomy may be a debatable issue, but we believe that preoperative cholangiography and/or intraoperative fluorescence cholangiography (18,19) is essential for reducing risk of bile duct injury especially in patients undergoing SILC. As single-incision surgery techniques advance, indications of SILC can be expanded gradually in future.

Interestingly, only 20% of potential candidates of SILC decided to undergo SILC after informed consent, most likely because the majority of patients in the present series prioritized safety of surgery over the advantages SILC demonstrated thorough randomized controlled trials (2,3), including better cosmetic outcomes, less postoperative pain, and shorter length of hospital stay compared to CLC. If further advancements in surgical techniques, such as robotic surgery (24) and intraoperative fluorescence cholangiography (17-20,25), enhance safety of SILC, the role of SILC in the treatment of cholecystolithiasis/cholecystitis may gain more presence in future.

In conclusion, SILC can be safely applied to patients...

The relationship between the tip position of an indwelling venous catheter and the subcutaneous edema

Summary The present observational study aimed to clarify the relationship between the tip position of an indwelling venous catheter and the subcutaneous edema using ultrasonography images. Data were obtained before catheter removal in a medical ward of a university hospital in Tokyo, Japan. Two hundred peripheral intravenous catheters (PIVCs) from 154 patients were observed just before removal. We analyzed data for 194 PIVCs from 150 patients. Subcutaneous edema was observed in 43.8% of ultrasonography images. According to the univariate analysis, insertion site, PIVC tip contact with the vessel wall, and irritant drug’s presence were selected as independent variables for logistic regression analysis. Both irritant drug and PIVC tip contact were associated with the presence of subcutaneous edema [adjusted odds ratio (OR) = 2.68, 95% confidence interval (CI) = 1.14-6.33; and OR = 2.01, 95% CI = 1.04-3.88, respectively]. To the best of our knowledge, this is the first study to use ultrasonography to simultaneously observe PIVC tip position and subcutaneous edema. Using ultrasonography to observe PIVC may be a useful method to understand these mechanisms. Medical staff should select an appropriate vein and indwelling catheter to avoid contact of PIVC tip with the vessel wall. Further studies exploring the causality of the relationship between subcutaneous edema, catheter placement, and thrombus formation is required. In addition, further development of nursing skills and medical devices to reduce mechanical stress is required.

Keywords: Intravenous therapy, peripheral intravenous catheters, subcutaneous tissue, ultrasonography

1. Introduction

Intravenous therapy using a peripheral intravenous catheter (PIVC) is a common and useful method for peripheral venous administration of medicine or fluid (1-3). However, treatment interruptions frequently occur in intravenous therapy because of accidental removal or signs and symptoms indicating complications (4-6). These problems not only lead to uncomfortable experiences for patients but are also costly in terms of repeated PIVC insertion (7,8).

Infiltration is one of the problems of intravenous therapy, because it can result in serious complications, including skin loss and necrosis (9). A report from the Veterans Administration of Puget Sound Health Care System showed that 33.7% of all complications during IV therapy with PIVC occurred because of infiltration (10). Therefore, clarifying the causes of infiltration can help prevent catheter failures.

The Infusion Nurses Society Standards of Practice Infiltration Scale defines infiltration as inadvertent leakage of a non-vesicant solution into surrounding
when a catheter was to be removed due to catheter failure, routine replacement, or completion of IV therapy. US examination was performed at bedside just before catheter removal. Characteristics of PIVC placement, such as insertion site, catheter size, and catheterization duration, were also recorded.

In addition, the researchers observed signs, such as swelling, redness, induration, bleeding, and symptoms, such as pain. Patient characteristics, such as age, sex, and history of present illness and intravenous fluid therapy, were collected from patients’ medical records.

2.3. US scanning technique

We used US diagnostic equipment (Hitachi Aloka Medical Ltd., Tokyo, Japan) with linear-array transducers (5-18.0 MHz). The focal range and image depth were set at 1.5-2 cm to determine the correct display range. Echo gain was set at 25 and the dynamic range at 65. Ultrasound gel (Aquasonic 100; Parker Laboratories Inc., Fairfield, NJ, USA) and gel pads (Sonar Pad; Nippon Bxi Inc., Tokyo, Japan) were used because transducer pressure resulted in vein disfiguration (Figure 1).

US examinations were performed by two researchers who received US training. The PIVC tip positions were the anatomic landmarks for identifying the US scanning point, with scanning starting at the insertion site and performed for more than 5 cm on both the short and long axes.

2.4. Data analysis

2.4.1. US images analysis

The PIVC tip position, intravenous thrombus, and edema of the subcutaneous fat layer were assessed by a certified sonographer with over 10 years of experience. The definitions of thrombus and subcutaneous edema were based on our previous study (12). Intravenous thrombus was defined as a marked echogenic mass with an uneven surface. Subcutaneous edema was defined by a homogeneous cobblestone appearance in the subcutaneous fat layer due to excessive fluid in the interstitium and a slightly edematous dermis. Presence or absence of subcutaneous edema and intravenous thrombus was determined using both transverse and longitudinal US images.

The PIVC tip position was defined as clear contact with the vessel wall; presence or absence of contact was determined using transverse US images.

2.4.2. Statistical analysis

Chi-square or Mann-Whitney U tests were used to compare PIVC placement between two patient groups (with and without subcutaneous edema).
2.5. Ethical considerations

Before participation, all patients and their families were informed about the purpose of the study, methods of measurement, management of individual information, consideration of safety, and right to withdraw from participation at any time. Written consent was obtained from all participating patients.

This study was approved by the Research Ethics Committee of the Graduate School of Medicine at the University of Tokyo (#10348).

3. Results

3.1. Participants and PIVC characteristics

In total, 293 patients consented to participate in the present study. Two hundred PIVCs from 154 patients were observed just before removal. Six PIVCs were excluded from analysis because US images were not obtained. Data for 194 PIVCs from 150 patients were analyzed. Of the participants, 88 (58.7%) were male; the mean age was 69.7 years, with a standard deviation...
(SD) of 12.7 years (range, 25-92 years). In addition, 81 patients (54%) had neoplasms (Table 1).

The most common catheter size was 22 gauge (81.4%) and almost all were inserted into the forearm (91.8%). The duration of catheterization was almost within 96 h (82.0%).

3.2. US findings

Subcutaneous edema was observed in 85 (43.8%) US images and was associated with the presence of infiltration ($p < 0.001$). Intravenous thrombus before PIVC removal was observed in 112 (60.9%) images, and PIVC tip was in clear contact with the vessel wall in 60 (33.3%) images.

3.3. Risk factors associated with subcutaneous edema

Patient characteristics, such as age and sex, and PIVC characteristics, such as catheter size, insertion site, and catheterization duration, were not associated with subcutaneous edema. The number of PIVCs used to administer irritant drug during catheterization was 36 (18.6%), which was significantly associated with subcutaneous edema ($p = 0.009$) and thrombus ($p = 0.001$). In this research, all irritant drugs were BFLUID®. The presence of PIVC tip contact was also associated with subcutaneous edema ($p = 0.038$). Intravenous thrombus was associated with subcutaneous edema ($p = 0.047$) (Table 2).

Following univariate analysis, insertion site, irritant drug, and presence of PIVC tip contact’s presence were included as independent variables for logistic regression analysis. The sex and age of patients were included as control variables. Multicollinearity was considered to be present between PIVC tip contact with the vessel wall and intravenous thrombus; therefore, intravenous thrombus was excluded. Administration of an irritant drug and presence of PIVC tip contact were associated with the presence of subcutaneous edema \[\text{adjusted odds ratio (OR)} = 2.68, 95\% \text{ confidence ratio}\]

\[P = 0.312\]

\[P = 0.377\]

\[P = 0.418\]

\[P = 0.125\]

\[P = 0.852\]

\[P = 0.312\]

\[P = 0.009\]

\[P = 0.038\]

\[P = 0.047\]

\[a\]Presence of edema of the subcutaneous fat layer before catheter removal by ultrasound. \[b\]Others: upper arm, dorsum of hand, wrist, cubital fossa, dorsum of foot, \[c\]Irritant drug: pH < 5 or ratio of osmotic pressure ≥ 3, \[d\]Mann-Whitney U test, \[e\]χ²-test. \[p < 0.05\]
Venous circulation (endothelial cell damage and cause the infusate to escape and high osmolarity relative to blood also affect venous PIVC tip positioned near the vessel wall. Extreme pH cells might be damaged by chemical stimulation from mechanical stimulation. In addition, venous endothelial may have been formed as an inflammatory reaction to from PIVC tip. Consequently, subcutaneous edema cells are directly damaged by mechanical stimulation PIVC tip contact. This suggests that venous endothelial associated with irritant infusate but also associated with that the presence of subcutaneous edema was not only clearly in contact with the vessel wall. It is noteworthy Our results showed that one third of PIVC tip was catheter within the vein. Although a relationship between the mechanism of the vessel wall damage and an increase in complications has not yet been revealed in detail (20), healthcare providers should carefully consider PIVC placement and the tip position in the vein. PIVC observation using US may be a useful method to develop understanding of these mechanisms. Medical staff should select an appropriate vein and indwelling catheter to avoid contact between PIVC tip and the vessel wall. Furthermore, even if PIVC tip is in contact with the vessel wall, developments in catheter design or material might reduce stimulation and inflammatory reactions. As we performed US observation just before catheter removal, we could not determine how long PIVC tip had stimulated a vascular wall. Moreover, it is not known exactly how PIVC position leads to complications. Further study exploring the causality of the relationship between subcutaneous edema, catheter placement, and thrombus formation is needed. In addition, further development is needed in nursing skills and medical devices to reduce mechanical stress.

4. Discussion

To the best of our knowledge, this is the first study using US to simultaneously examine PIVC tip position and subcutaneous edema. We found that the PIVC tip position was associated with subcutaneous edema. We focused on mechanical factors, one of the risk factors for infiltration and extravasation, because the subcutaneous tissue and vessel wall get damaged by inserting the needle. An indwelling catheter may also continuously stimulate the vessel wall during placement. Everitt prospectively observed intravenous catheters (fine-bore polyurethane) and vein caliber using B-mode ultrasound (7.5 MHz transducer), and suggested that the complication of infusion might be related to intravenous thrombus and that the initiating event was venous endothelial trauma by venipuncture and abrasion at the catheter tip or delivery of the feed (17). However, Everitt made no reference to the presence or absence of subcutaneous edema. In contrast, LaRue and Peterson suggested that the toxicant is no more diluted when a catheter's tip is positioned perpendicularly to the vessel wall; therefore, it may promote the incidence of chemically-induced phlebitis and subcutaneous edema (18). However, they did not observe the position of the catheter within the vein.

Our results showed that one third of PIVC tip was clearly in contact with the vessel wall. It is noteworthy that the presence of subcutaneous edema was not only associated with irritant infusate but also associated with PIVC tip contact. This suggests that venous endothelial cells are directly damaged by mechanical stimulation from PIVC tip. Consequently, subcutaneous edema may have been formed as an inflammatory reaction to mechanical stimulation. In addition, venous endothelial cells might be damaged by chemical stimulation from PIVC tip positioned near the vessel wall. Extreme pH and high osmolarity relative to blood also affect venous endothelial cell damage and cause the infusate to escape venous circulation (13,19).

Although a relationship between the mechanism of the vessel wall damage and an increase in complications has not yet been revealed in detail (20), healthcare providers should carefully consider PIVC placement and the tip position in the vein. PIVC observation using US may be a useful method to develop understanding of these mechanisms. Medical staff should select an appropriate vein and indwelling catheter to avoid contact between PIVC tip and the vessel wall. Furthermore, even if PIVC tip is in contact with the vessel wall, developments in catheter design or material might reduce stimulation and inflammatory reactions.

As we performed US observation just before catheter removal, we could not determine how long PIVC tip had stimulated a vascular wall. Moreover, it is not known exactly how PIVC position leads to complications. Further study exploring the causality of the relationship between subcutaneous edema, catheter placement, and thrombus formation is needed. In addition, further development is needed in nursing skills and medical devices to reduce mechanical stress.

Acknowledgements

We deeply appreciate all participants and medical staff who collaborated and helped us in our research. This research project was funded by a grant from the Japanese Ministry of Education, Culture, Sports, Science and Technology (Grant-in-Aid for Exploratory Research, 2014-2015, #26670915).

1. Introduction

Viral infections are serious conditions and are usually difficult to treat at the current point in time \cite{1}. Herpes simplex virus (HSV) can primarily be divided into two serotypes, \textit{i.e.} HSV-1 and HSV-2, and infection with HSV can lead to herpes simplex encephalitis, genital herpes, or cervical cancer, and is a risk factor for fetal congenital malformation \cite{2,3}. HSV-1 infection is a common and widespread disease that is characterized by lifelong persistence and periodic reactivation \cite{4}. Ribavirin is the one of the main drugs that is currently used to treat HSV-1 infection \cite{5}. However, mounting evidence has shown that the virus is becoming resistant to this drug due to long-term use \cite{6,7}. Consequently, the pressing challenge is to develop novel drugs to treat HSV-1 infection.

Traditional Chinese medicine (TCM) has attracted considerable attention in the search for antivirals because TCM has obvious advantages in the treatment of viral infections and TCM has a broad range of applications \cite{8}. Inulae Radix (Tu-Mu-Xiang) is a typical TCM that is usually used to treat bacterial or viral infection in China. Thus, the current study examined the anti-HSV-1 action of alantolactone, a main component found in Inulae Radix, \textit{in vitro}.

2. Materials and Methods

2.1. Agents

Alantolactone was obtained from Shanghai Yuanye Biological Technology Co. Ltd. (Shanghai, China). For an \textit{in vitro} assay, alantolactone was first dissolved in dimethyl sulfoxide (DMSO; Sigma-Aldrich) and further diluted in RPMI-1640 media (Hyclone) before use. Injectable ribavirin was purchased from Sanjing Pharmaceutical Co., Ltd. (Harbin, Heilongjiang, China). HSV-1 was obtained from the School of Basic Medicine, Nanjing University of Traditional Chinese Medicine (Nanjing, Jiangsu, China).

2.2. Cell line and cell culture

African green monkey kidney cells (Vero cells) were
obtained from the School of Basic Medicine, Nanjing University of Traditional Chinese Medicine. Briefly, cells were cultured in RPMI 1640 supplemented with 10% fetal bovine serum (FBS) at 37°C in a humid atmosphere (5% CO2-95% air). Cells were harvested by brief incubation in 0.02% (w/v) ethylenediaminetetraacetic acid (EDTA) in PBS.

2.3. Assay of the cytopathic effect (CPE) of the virus

A CPE-based assay was used to determine the structural changes in the host cells that are caused by viral invasion. Common examples of CPE include rounding of infected cells, fusion with adjacent cells to form syncytia, and the appearance of nuclear or cytoplasmic inclusion bodies (9). ‘−’ was recorded when none of the cells exhibited cytopathic effect; ‘+’ was recorded when 0-25% of cells exhibited a cytopathic effect; ‘++’ was recorded when 25-50% of cells exhibited a cytopathic effect; ‘+++’ was recorded when 50-75% of cells exhibited a cytopathic effect; and ‘++++’ was recorded when 75-100% of cells exhibited a cytopathic effect.

2.4. MTT assay

Cells (1 × 10⁴ per well) seeded in 96-well plates were exposed to increasing concentrations of alantolactone for specified times. After incubation for 72 h, a 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay was performed by adding 20 μL of MTT (5 mg/mL, Sigma-Aldrich) for 4 h (10). Light absorbance of the solution was measured at 490 nm on a microplate reader (Perkin-Elmer, USA).

3. Results and Discussion

3.1. Toxicity of the virus

Vero cells seeded in 96-well plates were exposed to decreasing concentrations of HSV-1 (10⁻¹, 10⁻², 10⁻³, 10⁻⁴, 10⁻⁵, 10⁻⁶, 10⁻⁷, 10⁻⁸, or 10⁻⁹ of stock virus solution) for 1 h. The virus solution was then removed. The cells were subsequently cultured in RPMI-1640 media for 72 h. A CPE-based assay was used to determine the damage caused by HSV-1 in Vero cells. Results indicated that Vero cells were all infected when the dilution of the virus was above 10⁻³, and the tissue culture 50% infective dose (TCID50) was calculated to be 10⁻⁶.33 according to the Reed-Muench method.

3.2. Effects of alantolactone on the viability of Vero cells

Vero cells seeded in 96-well plates were exposed to increasing concentrations of alantolactone for 72 h. The cells were then subjected to an MTT assay. Results revealed no obvious cytotoxic effects when the concentration of alantolactone was lower than 10⁻⁶ g/mL. In order to avoid the harmful effects of alantolactone on Vero cells, the concentration of alantolactone was set below 10⁻⁶ g/mL in the following antiviral assay.

3.3. Antiviral action of alantolactone on HSV-1

The effects of alantolactone on HSV-1 were determined using a CPE-based assay and an MTT assay. Results of the CPE-based assay indicated that alantolactone at a concentration of 10⁻⁶, 10⁻⁷, or 10⁻⁸ g/mL markedly inhibited viral infection (Table 1). However, alantolactone at a concentration of 10⁻⁷ g/mL exhibited more potent antiviral action. The reason why alantolactone had less potent antiviral activity at 10⁻⁶ g/mL than at 10⁻⁷ g/mL might be because a higher concentration of alantolactone has more of a cytotoxic effect on Vero cells, thus reducing the resistance of Vero cells to viral infection. Similar results were obtained using the MTT assay (Figure 1). Cell viability increased markedly when the alantolactone concentration was 10⁻⁶, 10⁻⁷, or 10⁻⁸ g/mL.

Table 1. Anti-HSV-1 action of alantolactone evaluated with a CPE-based assay

Figure 1. Alantolactone increased the viability of Vero cells infected with HSV-1.
mL. Alantolactone at a concentration of $10^{-7}$ g/mL provided the most protection from HSV-1 infection. The IC$_{50}$ of alantolactone was determined to be $10^{-7.4}$ g/mL.

The present study examined the antiviral action of alantolactone on HSV-1. Given the possible cytotoxic effects of alantolactone on Vero cells, the effects of alantolactone on the cell viability of Vero cells were first determined using an MTT assay. Results indicated that alantolactone at concentrations below $10^{-6}$ g/mL did not have a marked effect on the cell viability on Vero cells. Alantolactone at a concentration of $10^{-6}$, $10^{-7}$, or $10^{-8}$ g/mL inhibited viral infection and the viability of Vero cells increased markedly at these concentrations. These results suggest that alantolactone had antiviral action against HSV-1 in vitro and they provide evidence for use of Inulae Radix to treat HSV-1 infection. Studies to examine the antiviral action of alantolactone in vivo and the mechanisms underlying the action of alantolactone are warranted in the future.

Guide for Authors

1. Scope of Articles

BioScience Trends is an international peer-reviewed journal. BioScience Trends devotes to publishing the latest and most exciting advances in scientific research. Articles cover fields of life science such as biochemistry, molecular biology, clinical research, public health, medical care system, and social science in order to encourage cooperation and exchange among scientists and clinical researchers.

2. Submission Types

Original Articles should be well-documented, novel, and significant to the field as a whole. An Original Article should be arranged into the following sections: Title page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments, and References. Original articles should not exceed 5,000 words in length (excluding references) and should be limited to a maximum of 50 references. Articles may contain a maximum of 10 figures and/or tables.

Brief Reports definitively documenting either experimental results or informative clinical observations will be considered for publication in this category. Brief Reports are not intended for publication of incomplete or preliminary findings. Brief Reports should not exceed 3,000 words in length (excluding references) and should be limited to a maximum of 4 figures and/or tables and 10 references. A Brief Report contains the same sections as an Original Article, but the Results and Discussion sections should be combined.

Reviews should present a full and up-to-date account of recent developments within an area of research. Normally, reviews should not exceed 8,000 words in length (excluding references) and should be limited to a maximum of 100 references. Mini reviews are also accepted.

Policy Forum articles discuss research and policy issues in areas related to life science such as public health, the medical care system, and social science and may address governmental issues at district, national, and international levels of discourse. Policy Forum articles should not exceed 2,000 words in length (excluding references).

Case Reports should be detailed reports of the symptoms, signs, diagnosis, treatment, and follow-up of an individual patient. Case reports may contain a demographic profile of the patient but usually describe an unusual or novel occurrence. Unreported or unusual side effects or adverse interactions involving medications will also be considered. Case Reports should not exceed 3,000 words in length (excluding references).

Letters should present considered opinions in response to articles published in BioScience Trends in the last 6 months or issues of general interest. Letters should not exceed 800 words in length and may contain a maximum of 10 references.

3. Editorial Policies

Ethics: BioScience Trends requires that authors of reports of investigations in humans or animals indicate that those studies were formally approved by a relevant ethics committee or review board.

Conflict of Interests: All authors are required to disclose any actual or potential conflict of interest including financial interests or relationships with other people or organizations that might raise questions of bias in the work reported. If no conflict of interest exists for each author, please state "There is no conflict of interest to disclose".

Submission Declaration: When a manuscript is considered for submission to BioScience Trends, the authors should confirm that 1) no part of this manuscript is currently under consideration for publication elsewhere; 2) this manuscript does not contain the same information in whole or in part as manuscripts that have been published, accepted, or are under review elsewhere, except in the form of an abstract, a letter to the editor, or part of a published lecture or academic thesis; 3) authorization for publication has been obtained from the authors’ employer or institution; and 4) all contributing authors have agreed to submit this manuscript.

Cover Letter: The manuscript must be accompanied by a cover letter signed by the corresponding author on behalf of all authors. The letter should indicate the basic findings of the work and their significance. The letter should also include a statement affirming that all authors concur with the submission and that the material submitted for publication has not been published previously or is not under consideration for publication elsewhere. The cover letter should be submitted in PDF format. For example of Cover Letter, please visit http://www.biosciencetrends.com/download.php (Download Centre).

Copyright: A signed JOURNAL PUBLISHING AGREEMENT (JPA) form must be provided by post, fax, or as a scanned file before acceptance of the article. Only forms with a hand-written signature are accepted. This copyright will ensure the widest possible dissemination of information. A form facilitating transfer of copyright can be downloaded by clicking the appropriate link and can be returned to the e-mail address or fax number noted on the form (Please visit Download Centre). Please note that your manuscript will not proceed to the next step in publication until the JPA Form is received. In addition, if excerpts from other copyrighted works are included, the author(s) must obtain written permission from the copyright owners and credit the source(s) in the article.

Suggested Reviewers: A list of up to 3 reviewers who are qualified to assess the scientific merit of the study is welcomed. Reviewer information including names, affiliations, addresses, and e-mail should be provided at the same time the manuscript is submitted online. Please do not suggest reviewers with known conflicts of interest, including participants or anyone with a stake in the proposed research; anyone from the same institution; former students, advisors, or research collaborators (within the last three years); or close personal contacts. Please note that the Editor-in-Chief may accept one or more of the proposed reviewers or may request a review by other qualified persons.

Language Editing: Manuscripts prepared by authors whose native language is not English should have their work proofread by a native English speaker before submission. If not, this might delay the publication of your manuscript in BioScience Trends.

The Editing Support Organization can provide English proofreading, Japanese-English translation, and Chinese-English translation services to authors who want to publish in BioScience Trends and need assistance before submitting a manuscript. Authors can visit this organization directly at http://www.iacnhr.com/iac-eso/support.php?lang=en. IAC-ESO was established to facilitate manuscript preparation by researchers whose native language is not English and to help edit works intended for international academic journals.

4. Manuscript Preparation

Manuscripts should be written in clear, grammatically correct English and submitted as a Microsoft Word file in a single-column format. Manuscripts must be paginated and typed in 12-point Times New Roman font with 24-point line spacing. Please do not embed figures in the text. Abbreviations should be used as little as possible and should be explained at first mention unless the term is a well-known abbreviation (e.g. DNA). Single words should not be abbreviated.

Title Page: The title page must include 1) the title of the paper (Please note the title should be short, informative, and contain the major key words); 2) full name(s) and affiliation(s) of the author(s); 3) abbreviated names of the author(s), 4) full mailing address, telephone/fax numbers, and e-mail address of the corresponding author; and 5) conflicts of interest (if you have an actual or potential conflict of interest to disclose, it must be included as a footnote on the title page of the manuscript; if no conflict of interest
interest exists for each author, please state “There is no conflict of interest to disclose”). Please visit Download Centre and refer to the title page of the manuscript sample.

Abstract: The abstract should briefly state the purpose of the study, methods, main findings, and conclusions. For article types including Original Article, Brief Report, Review, Policy Forum, and Case Report, a one-paragraph abstract consisting of no more than 250 words must be included in the manuscript. For News and Letters, a brief summary of main content in 150 words or fewer should be included in the manuscript. Abbreviations must be kept to a minimum and non-standard abbreviations explained in brackets at first mention. References should be avoided in the abstract. Key words or phrases that do not occur in the title should be included in the Abstract page.

Introduction: The introduction should be a concise statement of the basis for the study and its scientific context.

Materials and Methods: The description should be brief but with sufficient detail to enable others to reproduce the experiments. Procedures that have been published previously should not be described in detail but appropriate references should simply be cited. Only new and significant modifications of previously published procedures require complete description. Names of products and manufacturers with their locations (city and state/country) should be given and sources of animals and cell lines should always be indicated. All clinical investigations must have been conducted in accordance with Declaration of Helsinki principles. All human and animal studies must have been approved by the appropriate institutional review board(s) and a specific declaration of approval must be made within this section.

Results: The description of the experimental results should be succinct but in sufficient detail to allow the experiments to be understood and interpreted by an independent reader. If necessary, subheadings may be used for an orderly presentation. All figures and tables should be referred to in the text.

Discussion: The data should be interpreted concisely without repeating material already presented in the Results section. Speculation is permissible, but it must be well-founded, and discussion of the wider implications of the findings is encouraged. Conclusions derived from the study should be included in this section.

Acknowledgments: All funding sources should be credited in the Acknowledgments section. In addition, people who contributed to the work but who do not meet the criteria for authors should be listed along with their contributions.

References: References should be numbered in the order in which they appear in the text. Citing of unpublished results, personal communications, conference abstracts, and theses in the reference list is not recommended but these sources may be mentioned in the text. In the reference list, cite the names of all authors when there are fifteen or fewer authors; if there are sixteen or more authors, list the first three followed by et al. Names of journals should be abbreviated in the style used in PubMed. Authors are responsible for the accuracy of the references. Examples are given below:

Tables: All tables should be prepared in Microsoft Word or Excel and should be arranged at the end of the manuscript after the References section. Please note that tables should not in image format. All tables should have a concise title and should be numbered consecutively with Arabic numerals. If necessary, additional information should be given below the table.

Figure Legend: The figure legend should be typed on a separate page of the main manuscript and should include a short title and explanation. The legend should be concise but comprehensive and should be understood without referring to the text. Symbols used in figures must be explained.

Figure Preparation: All figures should be clear and cited in numerical order in the text. Figures must fit a one- or two-column format on the journal page: 8.3 cm (3.3 in.) wide for a single column, 17.3 cm (6.8 in.) wide for a double column; maximum height: 24.0 cm (9.5 in.). Please make sure that the symbols and numbers appeared in the figures should be clear. Please make sure that artwork files are in an acceptable format (TIFF or JPEG) at minimum resolution (600 dpi for illustrations, graphs, and annotated artwork, and 300 dpi for micrographs and photographs). Please provide all figures as separate files. Please note that low-resolution images are one of the leading causes of article resubmission and schedule delays. All color figures will be reproduced in full color in the online edition of the journal at no cost to authors.

Units and Symbols: Units and symbols conforming to the International System of Units (SI) should be used for physicochemical quantities. Solidus notation (e.g. mg/kg, mg/mL, mol/mm/m) should be used. Please refer to the SI Guide www.bipm.org/en/si/ for standard units.

Supplemental data: Supplemental data might be useful for supporting and enhancing your scientific research and BioScience Trends accepts the submission of these materials which will be only published online alongside the electronic version of your article. Supplemental files (figures, tables, and other text materials) should be prepared according to the above guidelines, numbered in Arabic numerals (e.g., Figure S1, Figure S2, and Table S1, Table S2) and referred to in the text. All figures and tables should have titles and legends. All figure legends, tables and supplemental text materials should be placed at the end of the paper. Please note all of these supplemental data should be provided at the time of initial submission and note that the editors reserve the right to limit the size and length of Supplemental Data.

5. Submission Checklist

The Submission Checklist will be useful during the final checking of a manuscript prior to sending it to BioScience Trends for review. Please visit Download Centre and download the Submission Checklist file.

6. Online Submission

Manuscripts should be submitted to BioScience Trends online at http://www.biosciencetrends.com. The manuscript file should be smaller than 5 MB in size. If for any reason you are unable to submit a file online, please contact the Editorial Office by e-mail at office@biosciencetrends.com.

7. Accepted Manuscripts

Proofs: Galley proofs in PDF format will be sent to the corresponding author via e-mail. Corrections must be returned to the editor (proof-editing@biosciencetrends.com) within 3 working days.

Offprints: Authors will be provided with electronic offprints of their article. Paper offprints can be ordered at prices quoted on the order form that accompanies the proofs.

Page Charge: Page charges will be levied on all manuscripts accepted for publication in BioScience Trends ($140 per page for black white pages; $340 per page for color pages). Under exceptional circumstances, the author(s) may apply to the editorial office for a waiver of the publication charges at the time of submission.

JOURNAL PUBLISHING AGREEMENT (JPA)

Manuscript No.:

Title:

Corresponding Author:

The International Advancement Center for Medicine & Health Research Co., Ltd. (IACMHR Co., Ltd.) is pleased to accept the above article for publication in BioScience Trends. The International Research and Cooperation Association for Bio & Socio-Sciences Advancement (IRCA-BSSA) reserves all rights to the published article. Your written acceptance of this JOURNAL PUBLISHING AGREEMENT is required before the article can be published. Please read this form carefully and sign it if you agree to its terms. The signed JOURNAL PUBLISHING AGREEMENT should be sent to the BioScience Trends office (Pearl City Koishikawa 603, 2-4-5 Kasuga, Bunkyo-ku, Tokyo 112-0003, Japan; E-mail: office@bioscienceetrends.com; Tel: +81-3-5840-8764; Fax: +81-3-5840-8765).

1. Authorship Criteria
   As the corresponding author, I certify on behalf of all of the authors that:
   1) The article is an original work and does not involve fraud, fabrication, or plagiarism.
   2) The article has not been published previously and is not currently under consideration for publication elsewhere. If accepted by BioScience Trends, the article will not be submitted for publication to any other journal.
   3) The article contains no libelous or other unlawful statements and does not contain any materials that infringes upon individual privacy or proprietary rights or any statutory copyright.
   4) I have obtained written permission from copyright owners for any excerpts from copyrighted works that are included and have credited the sources in my article.
   5) All authors have made significant contributions to the study including the conception and design of this work, the analysis of the data, and the writing of the manuscript.
   6) All authors have reviewed this manuscript and take responsibility for its content and approve its publication.
   7) I have informed all of the authors of the terms of this publishing agreement and I am signing on their behalf as their agent.

2. Copyright Transfer Agreement
   I hereby assign and transfer to IACMHR Co., Ltd. all exclusive rights of copyright ownership to the above work in the journal BioScience Trends, including but not limited to the right 1) to publish, republish, derivate, distribute, transmit, sell, and otherwise use the work and other related material worldwide, in whole or in part, in all languages, in electronic, printed, or any other forms of media now known or hereafter developed and the right 2) to authorize or license third parties to do any of the above.

   I understand that these exclusive rights will become the property of IACMHR Co., Ltd., from the date the article is accepted for publication in the journal BioScience Trends. I also understand that IACMHR Co., Ltd. as a copyright owner has sole authority to license and permit reproductions of the article.

   I understand that except for copyright, other proprietary rights related to the Work (e.g. patent or other rights to any process or procedure) shall be retained by the authors. To reproduce any text, figures, tables, or illustrations from this Work in future works of their own, the authors must obtain written permission from IACMHR Co., Ltd.; such permission cannot be unreasonably withheld by IACMHR Co., Ltd.

3. Conflict of Interest Disclosure
   I confirm that all funding sources supporting the work and all institutions or people who contributed to the work but who do not meet the criteria for authors are acknowledged. I also confirm that all commercial affiliations, stock ownership, equity interests, or patent-licensing arrangements that could be considered to pose a financial conflict of interest in connection with the article have been disclosed.
