As of January 22, 2020, a total of 571 cases of the 2019-new coronavirus (2019-nCoV) have been reported in 25 provinces (districts and cities) in China. At present, there is no vaccine or antiviral treatment for human and animal coronavirus, so identifying the drug treatment options as soon as possible is critical for the response to the 2019-nCoV outbreak. Three general methods, which include existing broad-spectrum antiviral drugs using standard assays, screening of a chemical library containing many existing compounds or databases, and the redevelopment of new specific drugs based on the genome and biophysical understanding of individual coronaviruses, are used to discover the potential antiviral treatment of human pathogen coronavirus. Lopinavir/Ritonavir, Nucleoside analogues, Neuraminidase inhibitors, Remdesivir, peptide (EK1), arbidol, RNA synthesis inhibitors (such as TDF, 3TC), anti-inflammatory drugs (such as hormones and other molecules), Chinese traditional medicine, such ShuFengJieDu Capsules and Lianhuaqingwen Capsule, could be the drug treatment options for 2019-nCoV. However, the efficacy and safety of these drugs for 2019-nCoV still need to be further confirmed by clinical experiments.

SUMMARY

As of January 22, 2020, a total of 571 cases of the 2019-new coronavirus (2019-nCoV) have been reported in 25 provinces (districts and cities) in China. At present, there is no vaccine or antiviral treatment for human and animal coronavirus, so that identifying the drug treatment options as soon as possible is critical for the response to the 2019-nCoV outbreak. Three general methods, which include existing broad-spectrum antiviral drugs using standard assays, screening of a chemical library containing many existing compounds or databases, and the redevelopment of new specific drugs based on the genome and biophysical understanding of individual coronaviruses, are used to discover the potential antiviral treatment of human pathogen coronavirus. Lopinavir/Ritonavir, Nucleoside analogues, Neuraminidase inhibitors, Remdesivir, peptide (EK1), arbidol, RNA synthesis inhibitors (such as TDF, 3TC), anti-inflammatory drugs (such as hormones and other molecules), Chinese traditional medicine, such ShuFengJieDu Capsules and Lianhuaqingwen Capsule, could be the drug treatment options for 2019-nCoV. However, the efficacy and safety of these drugs for 2019-nCoV still need to be further confirmed by clinical experiments.

Keywords

2019-nCoV, Coronaviruses, pneumonia
new specific drugs based on the genome and biophysical understanding of individual coronaviruses (6). Examples include siRNA molecules or inhibitors targeting specific viral enzymes involved in the viral replication cycle, mAb targeting host receptor, inhibitor of host cell protease, inhibitor of host cell endocytosis virus, human derived or humanized mAb targeting S1 RBD and antiviral peptide targeting S2. Although most of these drugs have anti coronavirus activity in vitro and/or in vivo, their pharmacokinetic and pharmacodynamic properties, as well as side effect characteristics, have yet to be evaluated in animal and human trials. In addition, development of these drugs can allow drugs to become clinically useful treatment options, but it usually takes several years to provide reliable treatment for patients. The main drawback of this approach is that although many of the identified drugs show anti-coronavirus activity in vitro, most of them are not clinically useful because they are associated with immunosuppression or have a value of half the EC50 of anti-coronavirus, which is significantly higher than the peak serum concentration (Cmax) that can be achieved at the treatment dose.

In general, these three drug discovery methods are usually used together during the emerging coronavirus outbreak, and can be roughly divided into virus based and host based treatment selection candidate drug compounds.

For the current new coronavirus, according to the guidelines (7), IFN- alpha (5 million U bid inh) and lopinavir/ritonavir(400 mg/100 mg bid po) are recommended as antiviral therapy. IFN- alpha is a broad spectrum antiviral drug, which can be used to treat HBV. Lopinavir is one kind of protease inhibitor used to treat HIV infection, with ritonavir as a booster. Lopinavir and/or lopinavir litonavir have anti coronavirus activity in vitro. In Severe Acute Respiratory Syndrome (SARS) treatment, Hong Kong scholars found that compared with ribavirin alone, patients treated with lopinavir/ritonavir and ribavirin had lower risk of acute respiratory distress syndrome (ARDS) or death (8).

In addition, Nucleoside analogs have multiple mechanisms of action, including lethal mutagenesis, specific or non specific chain termination, and inhibition of nucleotide biosynthesis (9). Fabiravir and ribavirin are representatives of nucleoside analogs, which combined with fabiravir and oseltamivir in the treatment of severe influenza is better than oseltamivir alone (10).

Besides, Remdesivir may be the best potential drug for the treatment of 2019-nCoV. Animal experiments showed that compared with the control group, Remdesivir can effectively reduce the virus titer of mice infected with Middle East Respiratory Syndrome (Mers)-CoV, improve the lung tissue damage, and its effect is better than that of the treatment group treated with Lopinavir/Ritonavir combined with interferon-β (11). The drug has completed the phase III clinical trial for treatment of Ebola virus infection, and the pharmacokinetics and safety for the human body have relatively complete data (12). However, the efficacy and safety of Remdesivir in patients with 2019-nCoV infection still need to be further confirmed by clinical research.

Neuraminidase inhibitors (NAIs) such as oral oseltamivir, inhaled zanamivir, and intravenous peramivir are recommended as antiviral treatment in influenza (13). Oral oseltamivir has been widely used for 2019-nCoV or suspected cases in China hospitals. The mainstay for patients is initiation of antiviral medication as soon as possible after illness onset. It has shown that neuraminidase inhibitors are effective as empirical treatment in MERS-CoV infection (14), however, there is no exact evidence that oseltamivir is effective in the treatment of 2019-nCoV.

At present, some other types of drugs have been found to be effective in vitro, such as fusion peptide (EK1) (15), arbidol (16), RNA synthesis inhibitors (such as TDF, 3TC) anti-inflammatory drugs (such as hormones and other molecules), etc. In addition, Chinese medicine, such as ShuFengJieDu Capsules and Lianhuaqingwen Capsules, has also played a role in the prevention and treatment of new respiratory infectious diseases such as influenza A (H1N1) (17,18). However, the efficacy and safety of these drugs in 2019-nCoV need to be further confirmed by clinical experiments.

In general, there are no specific antiviral drugs or vaccines for 2019-nCoV. All of the drug options come from experience treating SARS, MERS or some other new influenza virus previously. Active symptomatic support remains key to treatment. These drugs above would be helpful and the efficacy needs to be further confirmed.
